(54) Title: MODULATION OF STEM AND PROGENITOR CELL DIFFERENTIATION, ASSAYS, AND USES THEREOF

(57) Abstract: The present invention relates to methods of modulating mammalian stem cell and progenitor cell differentiation. The methods of the invention can be employed to regulate and control the differentiation and maturation of mammalian, particularly human stem cells along specific cell and tissue lineages. The methods of the invention relate to the use of certain small organic molecules to modulate the differentiation of stem or progenitor cell populations along specific cell and tissue lineages, and in particular, to the differentiation of embryonic-like stem cells originating from a postpartum placenta or for the differentiation of early progenitor cells to a granulocytic lineage. Finally, the invention relates to the use of such differentiated stem or progenitor cells in transplantation and other medical treatments.

## **MODULATION OF STEM AND PROGENITOR CELL DIFFERENTIATION, ASSAYS, AND USES THEREOF**

This application claims benefit of United States Provisional Application Nos. 60/372,348, filed April 12, 2002; 60/437,348, filed December 31, 2002; and 60/437,350, 5 filed December 31, 2002, each of which is incorporated herein in its entirety.

### **1. INTRODUCTION**

The present invention relates to methods of modulating mammalian stem and/or progenitor cell differentiation. The methods of the invention can be employed to regulate and control the differentiation and maturation of mammalian, particularly human, stem and 10 progenitor cells along specific cell and tissue lineages. The methods of the invention relate to the use of certain small organic molecules to modulate the differentiation of stem cell populations along specific cell and tissue lineages, and in particular, to the differentiation of embryonic-like stem cells originating from a postpartum placenta or the modulation of early hematopoietic progenitor cells along a specific differentiation pathway, particularly a 15 granulocytic differentiation pathway. The invention also relates to the use of these organic molecules to modulate the differentiation of particular lineages of progenitor cells, such as CD34+, CD45+ and CD133+ progenitor cells. The invention also relates to the temporal aspects of progenitor cell development, and *in vitro* models based upon these temporal aspects. The invention further relates to the use of these modulated cells in prophylactic 20 and therapeutic methods, including in pharmaceutical compositions of such cells and/or small organic compounds. Finally, the invention relates to the use of such differentiated cells in transplantation and other medical treatments.

### **2. BACKGROUND OF THE INVENTION**

There is considerable interest in the identification, isolation and generation of human 25 stem and progenitor cells. Stem cells are totipotential or pluripotential precursor cells capable of generating a variety of mature cell lineages, and precursor cells are cells capable of generating cells of specific cell lineages. These abilities serve as the basis for the cellular differentiation and specialization necessary for organ and tissue development.

Recent success at transplanting stem and progenitor cells have provided new clinical 30 tools to reconstitute and/or supplement bone marrow after myeloablation due to disease, exposure to toxic chemical and/or radiation. Further evidence exists that demonstrates that stem cells can be employed to repopulate many, if not all, tissues and restore physiologic and

anatomic functionality. The application of stem cells in tissue engineering, gene therapy delivery and cell therapeutics is also advancing rapidly.

Many different types of mammalian and progenitor stem cells have been characterized. For example, embryonic stem cells, embryonic germ cells, adult stem cells or committed stem cells or progenitor cells are known. Certain stem cells have not only been isolated and characterized but have also been cultured under conditions to allow differentiation to a limited extent. However, a basic problem remains; that is, it has been difficult to control or regulate the differentiation of stem cells and progenitor cells, such as hematopoietic progenitor cells. Presently, existing methods of modulating the differentiation of these cells are crude and unregulatable, such that the cells differentiate into unwanted cell types, at unwanted times. Moreover, the yield of the product cells is typically low.

Furthermore, obtaining sufficient numbers of human stem cells for therapeutic or research purposes is problematic. Isolation of normally occurring populations of stem or progenitor cells in adult tissues has been technically difficult and costly, due, in part, to the limited quantity of stem or progenitor cells found in blood or tissue, and the significant discomfort involved in obtaining bone marrow aspirates. In general, harvesting of stem or progenitor cells from alternative sources in adequate amounts for therapeutic and research purposes is generally laborious, involving, *e.g.*, harvesting of cells or tissues from a donor subject or patient, culturing and/or propagation of cells *in vitro*, dissection, etc. With respect to stem cells in particular, procurement of these cells from embryos or fetal tissue, including abortuses, has raised religious and ethical concerns. The widely held belief that the human embryo and fetus constitute independent life has prompted governmental restrictions on the use of such sources for all purposes, including medical research. Alternative sources that do not require the use of cells procured from embryonic or fetal tissue are therefore desired for further progress in the use of stem cells clinically. There are, however, few viable alternative sources of stem or progenitor cells, particularly human stem or progenitor cells, and thus the supply is limited.

Hu *et al.* (WO 00/73421 entitled "Methods of isolation, cryopreservation, and therapeutic use of human amniotic epithelial cells," published December 7, 2000) discloses human amniotic epithelial cells derived from placenta at delivery that are isolated, cultured, cryopreserved for future use, or induced to differentiate. According to Hu *et al.*, a placenta is harvested immediately after delivery and the amniotic membrane separated from the chorion, *e.g.*, by dissection. Amniotic epithelial cells are isolated from the amniotic membrane according to standard cell isolation techniques. The disclosed cells can be

cultured in various media, expanded in culture, cryopreserved, or induced to differentiate. Hu *et al.* discloses that amniotic epithelial cells are multipotential (and possibly pluripotential), and can differentiate into epithelial tissues such as corneal surface epithelium or vaginal epithelium. The drawback of such methods, however, is that they are labor-intensive and the 5 yield of stem cells is very low.

Currently available methods for the *ex vivo* expansion of cell populations are also labor-intensive. For example, Emerson *et al.* (Emerson *et al.*, U.S. Patent No. 6,326,198 entitled "Methods and compositions for the *ex vivo* replication of stem cells, for the optimization of hematopoietic progenitor cell cultures, and for increasing the metabolism, GM-10 CSF secretion and/or IL-6 secretion of human stromal cells", issued December 4, 2001); discloses methods, and culture media conditions for *ex vivo* culturing of human stem cell division and/or the optimization of human hematopoietic progenitor stem cells. According to the disclosed methods, human stem cells or progenitor cells derived from bone marrow are cultured in a liquid culture medium that is replaced, preferably perfused, either continuously 15 or periodically, at a rate of 1 ml of medium per ml of culture per about 24 to about 48 hour period. Metabolic products are removed and depleted nutrients replenished while maintaining the culture under physiologically acceptable conditions.

Kraus *et al.* (Kraus *et al.*, U.S. Patent No. 6,338,942, entitled "Selective expansion of target cell populations," issued January 15, 2002) discloses that a predetermined target 20 population of cells may be selectively expanded by introducing a starting sample of cells from cord blood or peripheral blood into a growth medium, causing cells of the target cell population to divide, and contacting the cells in the growth medium with a selection element comprising binding molecules with specific affinity (such as a monoclonal antibody for CD34) for a predetermined population of cells (such as CD34 cells), so as to select cells of the 25 predetermined target population from other cells in the growth medium.

Rodgers *et al.* (U.S. Patent No. 6,335,195 entitled "Method for promoting hematopoietic and mesenchymal cell proliferation and differentiation," issued January 1, 2002) discloses methods for *ex vivo* culture of hematopoietic and mesenchymal stem cells and the induction of lineage-specific cell proliferation and differentiation by growth in the 30 presence of angiotensinogen, angiotensin I (AI), AI analogues, AI fragments and analogues thereof, angiotensin II (AII), AII analogues, AII fragments or analogues thereof or AII AT<sub>2</sub> type 2 receptor agonists, either alone or in combination with other growth factors and cytokines. The stem cells are derived from bone marrow, peripheral blood or umbilical cord blood. The drawback of such methods, however, is that such *ex vivo* methods for inducing proliferation

and differentiation of stem cells are time-consuming, as discussed above, and also result in low yields of stem cells.

Stem and progenitor cells have the potential to be used in the treatment of a variety of disorders, including malignancies, inborn errors of metabolism, hemoglobinopathies, and immunodeficiencies. One major area of use and research involving stem cells from cord blood or placenta has been the use of such cells to generate small quantities of cells for bone marrow and other related transplantations. However, to date, no one has described a method of producing substantial numbers of stem or progenitor cells, such as human CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells. Large numbers of the latter cells, in particular, would facilitate treatment methods using progenitor cells. The methods of the invention disclosed herein addresses this need.

Retinoids, such as vitamin A and retinoic acid (RA), have been known to affect differentiation of stem cells. For example, retinoic acid has been shown to inhibit proliferation of abnormally committed (chronic myelogenous leukemia) hematopoietic stem cells (Nadkarni *et al.* 1984, Tumori 70:503-505) and to induce differentiation and loss of self-renewal potential in promyelocytic leukemia cells (Melchner *et al.*, 1985, Blood 66(6):1469-1472). Retinoic acid has also been shown to induce differentiation of neurons from embryonic stem cells and to repress spontaneous mesodermal differentiation (Slager *et al.*, Dev. Genet. 1993;14(3):212-24, Ray *et al.*, 1997, J. Biol. Chem. 272(30): 18702-18708). Retinoic acid has further been shown to induce differentiation of transformed germ cell precursors (Damjanov *et al.*, 1993, Labor. Investig. 68(2):220-232), placental cell precursors (Yan *et al.*, 2001, Devel. Biol. 235: 422-432), and endothelial cell precursors (Hatzopoulos *et al.*, 1998, Development 125: 1457-1468). The effect of retinoids on differentiation, however, has yet to be completely understood such that it could be used as a regulatable means of controlling differentiation of stem cells.

The effects of folic acid analogues, such as aminopterin and amethopterin (methotrexate), on the differentiation of hematopoietic stem cells has been studied. Folic acid analogues are used as chemotherapeutic agents in acute lymphoblastic anemias and other blood proliferation disorders and cancers, and have been shown to effect differentiation of stem cells by killing off certain populations of stem cells (DeLoia *et al.*, 1998, Human Reproduction 13(4):1063-1069), and thus, would not be an effective tool for regulating differentiation of large quantities of stem cells for administration to a patient.

Several cytokines, such as IL-1, IL-2, IL-3, IL-6, IL-7, IL-11, as well as proteins such as erythropoietin, Kit ligand, M-CSF and GM-CSF have also been shown to direct differentiation of stem cells into specific cell types in the hematopoietic lineage (Dushnik-

Levinson *et al.*, 1995, Biol. Neonate 67:77-83), however, these processes are not well understood and still remain too crude and imprecise to allow for a regulatable means of controlling differentiation of stem cells.

To date, no one has described the use of compounds, such as the immunomodulatory 5 compounds discussed below, in the differentiation of stem cells or precursor cells. In particular, no one has demonstrated the use of such compounds to modulate the differentiation of progenitor cells, such as CD34<sup>+</sup> progenitor cells, away from a dendritic cell lineage, a capability useful in encouraging transplant immune tolerance. Likewise, no 10 one has described the use of the compounds described herein to expand the progenitor cell populations so as to produce a pharmaceutical composition containing such cells. Such expanded progenitor cell cultures would be useful in the treatment of graft-versus-host disease and the development of immune tolerance. Because control over stem and precursor cell differentiation can produce cell populations that are therapeutically useful, there is a need for the ability to control and regulate the differentiation of cells of myeloid 15 dendritic cell lineage, or early progenitor cells, such as human CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells, for the controlled production of dendritic cells and/or granulocytes.

### 3. SUMMARY OF THE INVENTION

The present invention provides methods of modulating mammalian, particularly human stem cell or progenitor cell differentiation. In particular, the methods of the 20 invention may be employed to regulate and control the differentiation and maturation of human stem cells along specific cell and tissue lineages. The invention encompasses the use of immunomodulatory small organic compounds, more preferably amino-substituted isoindolines, particularly the compounds Actimid™ or Revimid™, to effect such regulation and control. The invention further contemplated administration of these compounds to progenitor cells at 25 specific times to modulate their differentiation in specific ways.

The methods of the invention encompass the regulation of differentiation of a stem cell or progenitor cell into a specific cell lineage, including, but not limited to, a mesenchymal, hematopoietic, adipogenic, hepatogenic, neurogenic, gliogenic, chondrogenic, vasogenic, myogenic, chondrogenic, or osteogenic lineage. In particular 30 embodiment, the methods of the invention encompass the regulation of stem cell differentiation to a cell of a hematopoietic lineage.

The invention also encompasses the modulation of a committed cell to a specific cell type, *e.g.*, mesenchymal cell, hematopoietic cell, adipocyte, hepatocyte, neuroblast, glioblast, chondrocyte, endothelial cell (EC) progenitor, myocyte, chondrocyte, or osteoblast. In

specific embodiments, the invention encompasses the modulation of a committed hematopoietic progenitor cell to an erythrocyte, a thrombocyte, or a leukocyte (white blood cell) such as a neutrophil, monocyte, macrophage, eosinophil, basophil, mast cell, B-cell, T-cell, or plasma cell.

5 In another embodiment, the methods of the invention relate to modulating the differentiation of stem cells to cells of a hematopoietic lineage, in particular, CD34+, CD133+, and CD45+ hematopoietic lineages, and methods of producing prophylactically or therapeutically beneficial pharmaceutical compositions containing such cells. In another specific embodiment, the methods of the invention relate to modulating the differentiation of  
10 early progenitor cells into cells of a dendritic cell lineage or a granulocyte lineage, endothelial lineage, or cardiomyocyte lineage.

In another embodiment, the invention provides methods for regulating the differentiation of a progenitor cell into a hematopoietic lineage, particularly a dendritic cell or granulocytic lineage, endothelial lineage, neural lineage or cardiomyocyte lineage. In a  
15 specific embodiment, said progenitor cell is a CD34+ or CD133+ cell. Such regulation is accomplished by contacting the progenitor cells during culture with a compound of the invention. In one embodiment, said compound is an inhibitor of TNF- $\alpha$  activity. In a more specific embodiment, said compound is an immunomodulatory compound as described herein, or thalidomide or, more preferably, an amino-substituted isoindoline. In an even more specific  
20 embodiment, said compound is Actimid<sup>TM</sup> or Revimid<sup>TM</sup>

In another specific embodiment, the methods of the invention encompass the suppression of progenitor cell differentiation into a dendritic cell. In another specific embodiment, the invention provides a method for modulating the differentiation of progenitor cells during the first six days of culture to produce an expanded culture of such progenitor cells. In another embodiment, the methods of the invention encompass the promotion of early progenitor cell development into a granulocyte, which may be useful for fighting infections. The increase of granulocyte lineage committed progenitors (CD15<sup>+</sup> cells) can be of potential use in the reduction of neutropenia and its subsequent infectious complications that represent the most common dose-limiting toxicity of cancer chemotherapy. In another  
25 embodiment, the methods of the invention may be used to suppress dendritic cell differentiation, which is useful for mitigating the effects of graft-versus-host disease.

The progenitor cells of the invention, as modulated by a compound of the invention, are useful for transplantation (*i.e.*, hematopoietic reconstitution), and may be used in regenerative medicine as a renewable source of replacement cells and tissues (such as  
35 pancreatic, cardiac, hepatic, kidney, liver, brain, lung, bladder, intestinal or muscle cells) to

treat normal senescence, injury or diseases such as heart disease, stroke, Parkinson's disease, and Alzheimer's disease. The cells will also be useful in the determination of the intracellular biochemical pathways that mediate the action of the compounds of the invention. These cells may also be useful for the screening of new drugs and toxins, for example, to determine potential anti-cancer drugs, to understand the origins of birth defects, etc.

The methods of the invention may be used to suppress specifically the generation of red blood cells or erythropoietic colonies (BFU-E and CFU-E), while augmenting both the generation of leukocyte and platelet forming colonies (CFU-GM) and enhancing total colony forming unit production. The methods of the invention may be used not only to regulate the differentiation of stem cells, and progenitor cells such as CD34+ progenitor cells, but may also be used to stimulate the rate of colony formation, providing significant benefits to hematopoietic stem cell transplantation by improving the speed of bone marrow engraftment.

Any mammalian stem cell can be used in accordance with the methods of the invention, including but not limited to, stem cells isolated from cord blood, placenta and other sources. The stem cells may be isolated from any mammalian species, e.g., mouse, rat, rabbit, guinea pig, dog, cat, pig, sheep, cow, horse, monkey, etc., more preferably, a human. The stem cells may include pluripotent cells, i.e., cells that have complete differentiation versatility, that are self-renewing, and can remain dormant or quiescent within tissue. The stem cells may also include multipotent cells or committed progenitor cells. In one preferred embodiment, the invention utilizes stem cells that are viable, quiescent, pluripotent stem cells that exist within, or are later produced by, the full-term placenta, that is, such cells can be recovered following successful birth and placental expulsion, exsanguination and perfusion of the placenta, resulting in the production and recovery of as many as one billion nucleated cells, which yield 50 to 100 million multipotent and pluripotent stem cells. Such cells are referred to herein as human placental stem cells or embryonic-like stem cells.

In one particular embodiment of the invention, cells, for example cells endogenous to bone marrow or to a postpartum perfused placenta, including, but not limited to, embryonic-like stem cells, progenitor cells such as CD34+ or CD133+ cells, pluripotent cells and multipotent cells, are exposed to the compounds of the invention and induced to differentiate. The endogenous cells may be propagated *in vitro*. In another embodiment, the endogenous cells may be collected from the placenta and culture medium and cultured *in vitro* under conditions appropriate, and for a time sufficient, to induce differentiation to the desired cell type or lineage.

In another embodiment of the invention, the stem or progenitor cells are derived from other sources such as cord blood, peripheral blood or adult blood, and are exposed to the compounds of the invention and induced to differentiate. In a preferred embodiment, the differentiation is conducted *in vitro* under conditions appropriate, and for a time sufficient, to 5 induce differentiation into the desired lineage or cell type. The compounds of the invention are used in the differentiation/culture media by addition, *in situ* generation, or in any other manner that permits contact of the stem or progenitor cells with the compounds of the invention.

It has been discovered that the timing of the administration of the compounds of the 10 invention have a profound impact upon the differentiation of CD34<sup>+</sup> progenitor cells. Thus, in one embodiment of the invention, differentiation of CD34<sup>+</sup> progenitor cells into dendritic cells is delayed or suppressed by a method comprising contacting the progenitor cell on the first day of culture with a compound of the invention. In another embodiment, the development of CD1a<sup>+</sup> cells from CD34<sup>+</sup> progenitor cells is reduced or prevented by a 15 method comprising contacting said progenitor cells with a compound of the invention on the first day of culture. In another embodiment, the persistence of a CD1a<sup>+</sup> cell population derived from CD34<sup>+</sup> progenitor cells is increased by contacting said progenitor cells with a compound of the invention after culturing said progenitor cells for six days in the absence of said compound.

20 The present invention also encompasses methods of modulating the differentiation of early progenitor cells, such as human CD34<sup>+</sup> and CD133<sup>+</sup> cells, comprising contacting the progenitor cells at various times during the proliferative and differentiative phases with one or more of the compound(s) of the invention. Thus, in one embodiment, the invention encompasses a method of modulating the differentiation of the progenitor cells comprising 25 contacting said cells with one or more compound(s) of the invention on the first day of culture only. In another embodiment, said cells are contacted with said compound(s) in one dose on any day between the first day and the twelfth day of culture. In another embodiment, said cells are contacted at least two times with said compound(s), on different days, between days 0-12, inclusive. In yet another embodiment, said cells are contacted 30 with one or more compound(s) twice a day, once a day, or once every other day during the proliferative and/or differentiation phases. In another embodiment, said contacting is performed *in vitro*. In yet another embodiment, said contacting is performed *in vivo* in a subject. In a more specific embodiment, said subject is a human, a non-human mammal, an bird or a reptile.

In sum, exposure of endogenous or exogenous stem or progenitor cells which may be cultured in a postpartum perfused placenta, to compounds of the invention may occur while the cells are cultured in the placenta, or preferably, may occur *in vitro* after the cells have been recovered and removed from the placenta.

5        The invention encompasses the use of compounds that have TNF- $\alpha$  activity as modulators of stem and/or progenitor cell development. In specific embodiments, the compounds are immunomodulatory compounds such as classes of compounds known as IMiDs<sup>TM</sup>, including but not limited to thalidomide analogs, Actimid<sup>TM</sup> (Celgene Corp., Warren, NJ), and Revimid<sup>TM</sup> (Celgene Corp., Warren, NJ).

10      The invention also encompasses the transplantation of pretreated stem or progenitor cells to treat or prevent disease. In one embodiment, a patient in need of transplantation is also administered a compound of the invention before, during and/or after transplantation.

15      The invention further encompasses the use of a progenitor cell or specific cell type produced from a method of the invention. In other words, the invention encompasses the use of leukocytes, granulocytes, or dendritic cells made from the differentiation of a hematopoietic progenitor wherever said differentiation of the progenitor as modulated or regulated using a compound of the invention.

20      In other embodiments, the invention encompasses the control or regulation of stem cells *in vivo* by the administration of both a stem cell and a small molecule compound of the invention to a patient in need thereof.

25      In one embodiment, the invention provides a pharmaceutical composition comprising CD34+ or CD133+ progenitor cells that have been contacted with a compound of the invention, particularly one that inhibits the activity of TNF- $\alpha$ , in the first six days of culture, under conditions that promote proliferation and differentiation of said progenitor cells, and a pharmaceutically-acceptable carrier. In a specific embodiment, the pharmaceutical composition includes cells that have been collected and cryopreserved after six days of culture. In another specific embodiment, the cells of the pharmaceutical composition are CD34<sup>+</sup>CD38<sup>-</sup>CD34<sup>-</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD34<sup>+</sup> cells. In another specific embodiment, the compound with which the cells are contacted is an immunomodulatory compound of the invention, or thalidomide or a thalidomide analog. In another specific embodiment, the compound with which the cells are contacted is Actimid<sup>TM</sup> or Revimid<sup>TM</sup>.

30      In another embodiment, the invention also provides for method of making a pharmaceutical composition, comprising contacting CD34+ or CD133+ progenitor cells with a compound that inhibits TNF- $\alpha$  activity, wherein said progenitor cells are cultured for six days in a culture medium under culture conditions that allow proliferation and

differentiation of said progenitor cells; collecting said cells after six days of culture; and combining said cells with a pharmaceutically-acceptable carrier. In a specific embodiment of this method, said contacting is performed on the first day of culture. In another specific embodiment of this method, said contacting is performed at least twice during said six days  
5 of culture. In another specific embodiment of this method, said compound is a small immunomodulatory compound of the invention. In another specific embodiment of this method, said compound is Actimid™ or Revimid™. In yet another specific embodiment of this method, said progenitor cells have been isolated from other blood cells prior to said culturing. In another specific embodiment of this method, said culture medium additionally  
10 contains GM-CSF and TNF- $\alpha$ . In more specific embodiment of this method, said Actimid™ or Revimid™ is present in a concentration of between 0.1  $\mu$ M and 10.0  $\mu$ M. In another more specific embodiment of this method, said Actimid™ or Revimid™ is present at a concentration of 1.0  $\mu$ M. In another specific embodiment of this method, said cells are cryopreserved after said collecting.

15 The invention further provides a method for expanding a progenitor cell population in a mammalian subject, comprising administering a therapeutically effective amount of CD34+ or CD133+ progenitor cells and either Actimid™ or Revimid™ to said recipient mammalian subject. In specific embodiment of this method, said progenitor cells are differentiated in the recipient mammalian subject. In another specific embodiment of this  
20 method, said progenitor cells are administered to said subject in a cell preparation that is substantially free of red blood cells. In another specific embodiment of this method, said progenitor cells are administered to the recipient mammalian subject in a cell preparation that comprises bone marrow cells, placental cells, cord blood cells or PBMCs. In another specific embodiment of this method, said progenitor cells are administered to the recipient  
25 mammalian subject in conjunction with a carrier. In another specific embodiment of this method, said progenitor cell is a CD34+CD133+ progenitor cell. In another specific embodiment of this method, the progenitor cells express incorporated genetic material of interest.

30 The present invention also provides the cells that are produced by the above methods that are useful as pharmaceutical compositions.

In yet other embodiments, the invention encompasses methods of conditioning stem cells or progenitor cells, for example, CD34+ progenitor cells, following cryopreservation and thawing, to counteract the deleterious effects of cryopreservation and exposure to cryopreservatives on the stem cells. In certain embodiments, the invention provides methods  
35 of conditioning stem cells following cryopreservation and thawing, to counteract the deleterious

effects of exposure to cryopreservatives (*e.g.*, DMSO) on the proliferative and migratory capacity of stem cells.

### 3.1. DEFINITIONS

As used herein, the term "bioreactor" refers to an *ex vivo* system for propagating cells, 5 producing or expressing biological materials and growing or culturing cells tissues, organoids, viruses, proteins, polynucleotides and microorganisms.

As used herein, "DC cells" refers to dendritic cells.

As used herein, "early progenitor cell" means a CD34+ progenitor cell, a CD133<sup>+</sup> progenitor cell, or the mammalian, avian or reptilian equivalent of either.

10 As used herein, the term "embryonic stem cell" refers to a cell that is derived from the inner cell mass of a blastocyst (*e.g.*, a 4- to 5-day-old human embryo) and that is pluripotent.

15 As used herein, the term "embryonic-like stem cell" refers to a cell that is not derived from the inner cell mass of a blastocyst. As used herein, an "embryonic-like stem cell" may also be referred to as a "placental stem cell." An embryonic-like stem cell is preferably pluripotent. However, the stem cells which may be obtained from the placenta include embryonic-like stem cells, multipotent cells, and committed progenitor cells. According to the methods of the invention, embryonic-like stem cells derived from the placenta may be collected from the isolated placenta once it has been exsanguinated and 20 perfused for a period of time sufficient to remove residual cells. Preferably, the embryonic-like stem cells are human, though they may be derived from any mammal.

As used herein, the term "exsanguinated" or "exsanguination," when used with respect to the placenta, refers to the removal and/or draining of substantially all cord blood from the placenta. In accordance with the present invention, exsanguination of the placenta can be 25 achieved by, for example, but not by way of limitation, draining, gravity induced efflux, massaging, squeezing, pumping, etc. In a preferred embodiment, exsanguination of the placenta may further be achieved by perfusing, rinsing or flushing the placenta with a fluid that may or may not contain agents, such as anticoagulants, to aid in the exsanguination of the placenta.

30 As used herein, the term "perfuse" or "perfusion" refers to the act of pouring or passaging a fluid over or through an organ or tissue, preferably the passage of fluid through an organ or tissue with sufficient force or pressure to remove any residual cells, *e.g.*, non-attached cells from the organ or tissue. As used herein, the term "perfusate" refers to the fluid collected following its passage through an organ or tissue. In a preferred embodiment, 35 the perfusate contains one or more anticoagulants.

As used herein, the term "endogenous cell" refers to a "non-foreign" cell, *i.e.*, a "self" or autologous cell, that is derived from the placenta.

As used herein, the term "exogenous cell" refers to a "foreign" cell, *i.e.*, a heterologous cell (*i.e.*, a "non-self" cell derived from a source other than the placental donor) or autologous 5 cell (*i.e.*, a "self" cell derived from the placental donor) that is-derived from an organ or tissue other than the placenta.

As used herein, "immunomodulatory compound" refers to the compounds disclosed in Section 5.3, below.

As used herein, the term "organoid" refers to an aggregation of one or more cell types 10 assembled in superficial appearance or in actual structure as any organ or gland of a mammalian body, preferably the human body.

As used herein, the term "multipotent cell" refers to a cell that has the capacity to grow into any of subset of the mammalian body's approximately 260 cell types. Unlike a pluripotent cell, a multipotent cell does not have the capacity to form all off the cell types.

15 As used herein, the term "pluripotent cell" refers to a cell that has complete differentiation versatility, *i.e.*, the capacity to grow into any of the mammalian body's approximately 260 cell types. A pluripotent cell can be self-renewing, and can remain dormant or quiescent within a tissue. Unlike a totipotent cell (*e.g.*, a fertilized, diploid egg cell), an embryonic stem cell cannot usually form a new blastocyst.

20 As used herein, the term "progenitor cell" refers to a cell that is committed to differentiate into a specific type of cell or to form a specific type of tissue.

As used herein, the term "stem cell" refers to a master cell that can reproduce indefinitely to form the specialized cells of tissues and organs. A stem cell is a developmentally pluripotent or multipotent cell. A stem cell can divide to produce two 25 daughter stem cells, or one daughter stem cell and one progenitor ("transit") cell, which then proliferates into the tissue's mature, fully formed cells.

As used herein, the term "totipotent cell" refers to a cell that is able to form a complete embryo (*e.g.*, a blastocyst).

#### 4. BRIEF DESCRIPTION OF THE FIGURES

30 FIG. 1. Bar graph indicating results of culturing cord blood CD34+ cells in the presence of Thalidomide (THD), Actimid™, and Revimid™ at concentrations of 1 µg/ml and 10 µg/ml. An equal volume of DMSO was used as a negative control. Hematopoietic colonies of burst forming units-erythroid (BFU-E), colony forming units-erythroid (CFU-E), colony forming units-granulocyte macrophage (CFU-GM) and total numbers of colonies (CFU-

Total) were scored under the light microscope at day 14 of culture. Y-axis: numbers of colonies. See Section 6.1 for details.

FIGS. 2(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to Actimid™ and Revimid™ inhibits erythropoiesis and expansion of CD34+CD38- cells.  
5 Cord blood CD45+ cells were cultured for 14 days with cytokines IL3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Thalidomide ("Thal") (5 µg/ml). E. Actimid™ (5 µg/ml). F. Revimid™ (5 µg/ml). X-axis: relative intensity of Gly-A (FL1-H) staining. Y-axis: relative intensity of CD34 (F 2-H) staining. See Section 6.1 for details.  
10

FIGS. 3(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to Actimid™ or Revimid™ inhibits the expression of CXCR4 on human cord blood CD34+ cells in 14 days of culture with cytokines IL3, KL and G-CSF. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, CD45+ cells. C. DMSO (0.3 µg/ml). D. Thal (0.3 µg/ml). E. Actimid™ (0.3 µg/ml). F. Revimid™ (0.3 µg/ml). X-axis: relative intensity of CD34 (FL1-H) staining. Y-axis: relative intensity of CXCR4 (FL2-H) staining. See Section 6.2 for details.  
15

FIGS. 4(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to 20 Actimid™ or Revimid™ stimulates the expansion of CD34+ and/or CD34+CD38- cell populations. Cord blood CD45+ cells were cultured for 14 days with cytokines IL3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (0.3 µg/ml). D. Thal (0.3 µg/ml). E. 25 Actimid™ (0.3 µg/ml). F. Revimid™ (0.3 µg/ml). X-axis: relative intensity of CD 38 (FL1-H) staining. Y-axis: relative intensity of CD34 (FL2-H) staining. See Section 6.2 for details.

FIGS. 5(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to 30 Actimid™ or Revimid™ produces significant preservation of human cord blood progenitor cells. Cord blood CD45+ cells were cultured for 14 days with cytokines IL3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Thal (5 µg/ml). E. Actimid™ (5 µg/ml). F. Revimid™ (5 µg/ml). X-axis: relative intensity of CD 38 (FL1-H) staining. Y- 35 axis: relative intensity of CD34 (FL2-H) staining. See Section 6.2 for details.

FIGS. 6(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to Actimid™ and Revimid™ inhibits CXCR4 expression and expands the population of CD45+ cells. Cord blood CD45+ cells were cultured for 14 days with cytokines IL3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Thal (5 µg/ml). E. Actimid™ (5 µg/ml). F. Revimid™ (5 µg/ml). X-axis: relative intensity of CD45 (FL1-H) staining. Y-axis: relative intensity of CXCR4 (FL2-H) staining. See Section 6.2 for details.

FIGS. 7(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to Actimid™ and Revimid™ produces an expansion in number of CD34+ progenitor cells and increases production of granulocytes and monocytes. Cord blood CD45+ cells were cultured for 14 days with cytokines 1L3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Thal (5 µg/ml). E. Actimid™ (5 µg/ml). F. Revimid™ (5 µg/ml). X-axis: relative intensity of CD11b (FL1-H) staining. Y-axis: relative intensity of CD34 (FL2-H) staining. See Section 6.2 for details.

FIGS. 8(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to Actimid™ and Revimid™ expands CD34+ progenitor cells and counteracts the DMSO-mediated repression of monocyte production. Cord blood CD45+ cells were cultured for 14 days with cytokines IL3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Thal (5 µg/ml). E. Actimid™ (5 µg/ml). F. Revimid™ (5 µg/ml). X-axis: relative intensity of CD14 expression (FL1-H) staining. Maxis: relative intensity of CD34 (FL2-H) staining. See Section 6.3 for details.

FIGS. 9(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to Actimid™ shows minor suppressive effects on the differentiation into B cells. Cord blood CD45+ cells were cultured for 14 days with cytokines IL3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Thal (5 µg/ml). E. Actimid™ (5 µg/ml). F. Revimid™ (5 µg/ml). X-axis: relative intensity of CD38 (FL1-H) staining. Y-axis: relative intensity of CD19 (FL2-H) staining. See Section 6.3 for details.

FIGS. 10(A-F). Flow cytograms. Exposure of human cord blood CD45+ cells to Actimid™ and Revimid™ overcomes the repression of CXCR5 produced by exposure to DMSO. Cord blood CD45+ cells were cultured for 14 days with cytokines IL3, IL6, G-CSF, Epo and KL. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Thal (5 µg/ml). E. Actimid™ (5 µg/ml). F. Revimid™ (5 µg/ml). X-axis: relative intensity of CXCR5 (FL1 -H) staining. Y-axis: relative intensity of CD34 (FL2-H) staining. See Section 6.3 for details.

FIGS. 11(A-E). Flow cytograms. Exposure of human cord blood mononucleated cells (MNCs) to Actimid™ and Revimid™ increases the CD34+CD38+ cell population. Percentages indicated on each cytogram. indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Actimid™ (5 µg/ml). E. Revimid™ (5 µg/ml). X-axis: relative intensity of CD38 (FL1-H) staining. Y-axis: relative intensity of CD34 (FL2-H) staining. See Section 6.3 for details.

FIGS. 12(A-E). Flow cytograms. Exposure of MNCs to Actimid™ and Revimid™ down-regulates the CXCR4+CD45+ cell population, but increases the CXCR4+CD45- cell population. Percentages indicated on each cytogram indicate the percentage of the cell population expressing a particular combination of markers. A. Control, immunoglobulin (Ig). B. Control, no compound added. C. DMSO (5 µg/ml). D. Actimid™ (5 µg/ml). E. Revimid™ (5 µg/ml). X-axis: relative intensity of CD45 (FL1-H) staining. Y-axis: relative intensity of CXCR4 (FL2-H) staining. See Section 6.3 for details.

FIGS. 13(A-E). Flow cytograms. The effect of Thalomid, Actimid™ and Revimid™ on lineage commitment of differentiating hematopoietic progenitors in the nucleated cell fraction of umbilical cord blood. The flow cytograms show that Actimid™ and Revimid™ increase the percentage of monocyte lineage cells compared to control, indicating that there is a modulation of differentiation which shifts towards lineages which give rise to lymphoid and myeloid cells. A. Control, immunoglobulin (Ig). B. DMSO (5 µg/ml). C. Thal (5 µg/ml). D. Actimid™ (5 µg/ml). E. Revimid™ (5 µg/ml). See Section 6.4 for details.

FIG. 14. Outline of study of effect of Actimid™ on CD34+ cell differentiation and maturation into DC cells. CD34<sup>+</sup> cells were cultured in the presence or absence of 1.0 µM Actimid™ and DMSO (dimethylsulfoxide) during either the expansion and maturation phase (day 1 to day 12) or during the maturation phase (day 6 to day 12).

Immunohistochemical markers were assessed at day 6 or day 12 using FITC and PE conjugated monoclonal antibodies. See Section 6.6 for details.

FIGS. 15(A-D). Flow cytograms showing phenotypic characteristics of day 6 CD34+ cells, exposed to Actimid<sup>TM</sup> from day 1. Actimid<sup>TM</sup> almost completely suppressed the development of CD86<sup>+</sup>CD1a<sup>+</sup> cells. Cells were double-labeled with CD1a FITC and CD14 PE or CD1a FITC and CD86 PE. A: CD86<sup>+</sup>CD1<sup>+</sup> cells generated from CD34<sup>+</sup> cells treated with DMSO (control). B: CD14<sup>+</sup>CD1<sup>+</sup> cells generated from CD34<sup>+</sup> cells treated with DMSO (control). C: CD86<sup>+</sup>CD1<sup>+</sup> cells generated from CD34<sup>+</sup> cells treated with Actimid<sup>TM</sup>. D: CD14<sup>+</sup>CD1<sup>+</sup> cells generated from CD34<sup>+</sup> cells treated with Actimid<sup>TM</sup>. Percentages in each cytogram indicate the percentage of cells expressing a particular combination of markers. See Section 6.6 for details.

FIGS. 16(A-D). Flow cytograms showing effect at day 6 of Actimid<sup>TM</sup> exposure during expansion phase (day 1 to day 6) on CD34+ cells. CD34<sup>+</sup>CD38<sup>-</sup> cells exposed to Actimid<sup>TM</sup> differentiated into CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> cells after 6 days. Cells were double-labeled with CD33 FITC and CD83 PE or C38 PE and CD34 PE. A: Cells treated with DMSO and labeled for CD34 and CD38. B: cells treated with DMSO and labeled for CD83 and CD33. C: cells treated with Actimid<sup>TM</sup> and labeled for CD34 and CD38. D: cells treated with Actimid<sup>TM</sup>. Percentages in each cytogram indicate the percentage of cells expressing a particular combination of markers. See Section 6.6 for details.

FIG. 17. Actimid<sup>TM</sup> induces a shift in CD34<sup>+</sup> cell-derived cell populations from culture day 0 to day 6. Cells were cultured from day 0 to day 6 in the presence of different concentrations of Actimid<sup>TM</sup>, then double labeled with CD34 and CD38 or CD1a and CD14. Actimid<sup>TM</sup> causes a marked increase in CD34<sup>+</sup>CD38<sup>-</sup> cells and a decrease in CD1a<sup>+</sup>CD14<sup>-</sup> cells. See Section 6.6 for details.

FIG. 18. Phenotypic modifications at day 6 of CD34<sup>+</sup> cells treated for various times with Actimid<sup>TM</sup>. Cells were plated and cultured for 6 days. Cells were treated with Actimid<sup>TM</sup> from day 0 to day 1 only, day 0 to day 2 only, day 0 to day 3 only, day 0 to day 4 only, day 0 to day 5 only, or day 0 to day 6. For incubations less than 6 days, Actimid<sup>TM</sup> was washed out on the indicated day and cells were resuspended in DMSO. At 6 days, the cells were labeled with CD34 and CD38 or CD1a and CD14. See Section 6.6 for details.

FIGS. 19(A-B). Phenotypic modifications at day 6 of CD34<sup>+</sup> progenitor cells treated with single or multiple doses of Actimid<sup>TM</sup>. FIG. 19A: Condition 1: single dose of Actimid<sup>TM</sup> at day 0; condition 2: Actimid<sup>TM</sup> administered at day 0 and day 4; condition 3: Actimid<sup>TM</sup> administered at day 0, day 2, and day 4. Y axis indicates the percentage of cells expressing the particular marker or combination of markers. FIG. 19B: Condition 1: single

dose of Actimid™ at day 0; condition 2: Actimid™ administered at day 0, day 4, day 6 and day 8; condition 3: Actimid™ administered at day 0, day 2, day 4, day 6 and day 8. Cells were assessed for expression of CD11c and CD15, a granulocytic marker. Y axis indicates the percentage of CD11c<sup>+</sup>CD15<sup>-</sup> and CD11c<sup>-</sup>CD15<sup>+</sup> cells contacted with Actimid™ or

5 DMSO (control). See Section 6.6 for details.

FIGS. 20(A-F). Flow cytograms of dendritic cells at day 12 generated from CD34+ cells exposed to Actimid™ (1μM) from day 1 to day 12. Actimid™ causes the decrease of co-stimulatory molecules CD86 and CD80 at day 12 as compared to control. Cells were double-labeled with CD1a FITC and CD86 PE antibodies, CD1a FITC and CD80 PE antibodies, or CD1a FITC and CD14 PE antibodies. A: Cells treated with DMSO and stained at day 12 for CD86 and CD1a. B: Cells treated with DMSO and stained at day 12 for CD80 and CD1a. C: Cells treated with DMSO and stained at day 12 for CD14 and CD1a. D: Cells treated with Actimid™ and stained at day 12 for CD86 and CD1a. E: Cells treated with Actimid™ and stained at day 12 for CD80 and CD1a. F: Cells treated with Actimid™ and stained at day 12 for CD14 and CD1a. Percentages in each cytogram indicate the percentage of cells expressing a particular combination of markers. See Section 6.6 for details.

FIGS. 21(A-D). Flow cytograms of dendritic cells at day 12 generated from CD34+ cells exposed to Actimid™ (1μM) from day 1 to day 12. Exposure to Actimid™ results in a modulation of adhesion molecule CD54 expression, causing a decrease in the expression of CD54<sup>bright</sup> and an increase expression of CD54<sup>dim</sup> relative to control (compare subpanels E and F in FIG. 21D). A: Cells treated with DMSO and stained for HLA-DR and with IgG1. B: Cells treated with DMSO and stained for CD54 and CD40. C: Cells treated with Actimid™ and stained for HLA-DR and with IgG1. D: Cells treated with Actimid™ and stained for CD54 and CD40. Percentages in each cytogram indicate the percentage of cells expressing a particular combination of markers. See Section 6.6 for details.

FIGS. 22(A-B). Actimid™ promotes granulocytic differentiation from CD34<sup>+</sup> progenitor cells. Flow cytograms of CD34<sup>+</sup> cells grown for 12 days in the presence of DMSO (FIG. 22A) or Actimid™ (FIG. 22B), then labeled with antibody to the granulocyte marker CD15. Percentages in each cytogram indicate the percentage of cells expressing a particular combination of markers. See Section 6.6 for details.

FIGS. 23(A-D). Actimid™ does not induce apoptosis of CD1a<sup>+</sup> or CD14<sup>+</sup> precursors. Flow cytograms of CD1a<sup>+</sup>CD14<sup>-</sup> and CD1a<sup>-</sup>CD14<sup>+</sup> isolated cells (DC progenitors). CD34<sup>+</sup> progenitors cells were cultured for a period of 6 days in the presence of SCF, Flt-3L, GM-CSF and TNF-α. At day 6, CD1a<sup>+</sup>CD14<sup>-</sup> and CD1a<sup>-</sup>CD14<sup>+</sup> cells were isolated by

magnetic cell sorting (Miltenyi), and purified CD1a<sup>+</sup>CD14<sup>-</sup> and CD1a<sup>-</sup>CD14<sup>+</sup> populations were cultured for an additional 2 days in the presence of GM-CSF and TNF- $\alpha$  with or without Actimid<sup>TM</sup> (1  $\mu$ M). Apoptotic cells were then monitored using Annexin V-FITC staining, a marker for apoptosis, in combination with propidium iodide (PI), a viability probe. Percentages in each cytogram indicate the percentage of cells staining positive for Annexin V-FITC and/or propidium iodide. The number of cells positive for Annexin V-FITC was comparable in Actimid<sup>TM</sup>-treated and control cells (compare particularly B3 and B4 in each cytogram). A: CD1a<sup>+</sup>CD14<sup>-</sup> cells treated with DMSO. B: CD1a<sup>+</sup>CD14<sup>-</sup> cells treated with Actimid<sup>TM</sup>. C: CD1a<sup>-</sup>CD14<sup>+</sup> cells treated with DMSO. D: CD1a<sup>-</sup>CD14<sup>+</sup> cells treated with Actimid<sup>TM</sup>. See Section 6.6 for details.

FIGS. 24(A-D). Flow cytograms of CD34<sup>+</sup> cells grown for 12 days in the presence or absence of Actimid<sup>TM</sup>. Actimid<sup>TM</sup> causes a decrease in mannose receptor-mediated endocytosis, as demonstrated by decreased uptake of FITC-labeled dextran relative to DMSO control. A: DMSO and 4°C. B: Actimid<sup>TM</sup> and 4°C. C: DMSO and 37°C. D: Actimid<sup>TM</sup> and 37°C. Percentage in each cytogram indicates the fraction of cells exhibiting endocytosis. See Section 6.6 for details.

FIGS. 25(A-D). Flow cytograms of CD34<sup>+</sup> cells cultured for 12 days, and cultured in the presence or absence of Actimid<sup>TM</sup> from days 6-12. Culturing in the presence of Actimid<sup>TM</sup> on days 6-12, after culture from days 1-5 in the absence of Actimid<sup>TM</sup>, results in mannose receptor-mediated endocytosis comparable to that of DMSO control. Percentage in each cytogram indicates the fraction of cells exhibiting endocytosis. A: DMSO and 4°C. B: Actimid<sup>TM</sup> and 4°C. C: DMSO and 37°C. D: Actimid<sup>TM</sup> and 37°C. See Section 6.6 for details.

FIG. 26. Actimid<sup>TM</sup> reduces the capacity of CD34<sup>+</sup> cells cultured for 12 days to present antigen. CD34<sup>+</sup> cells were cultured for 12 days in the presence or absence of Actimid<sup>TM</sup>; Actimid<sup>TM</sup>-treated cells, at day 12, show a substantially decreased stimulation index as compared to DMSO control. See Section 6.6 for details.

FIG. 27. Actimid<sup>TM</sup> has little APC reduction activity on CD34<sup>+</sup> cells cultured in Actimid<sup>TM</sup> from day 6 to day 12. CD34<sup>+</sup> cells were cultured for five days, the cultured in the presence or absence of Actimid<sup>TM</sup>. Antigen-presenting capacity of treated cells is comparable to that of control, DMSO-treated cells. See Section 6.6 for details.

FIG. 28. Differentiation pathway of CD34<sup>+</sup> hematopoietic progenitor cells cultured in the presence of GM-CSF and TNF- $\alpha$ .

FIG. 29. Summary chart showing the effect of Actimid<sup>TM</sup> on the differentiation pathway of CD34<sup>+</sup> hematopoietic progenitor cells cultured in the presence of GM-CSF and TNF- $\alpha$ . See Section 6.6 for details.

FIG. 30. Diagram showing maturation conditions for murine Sca<sup>+</sup>Lin-  
5 hematopoietic progenitor cells. Cells were grown for 9 days in the presence of stem cell factor (SCF), Flt-3L, granulocyte macrophage-colony stimulating factor (GM-CSF) and macrophage-colony stimulating factor (MCSF) in the presence of DMSO at 0.1% (control), 10  $\mu$ M Actimid<sup>TM</sup> or 10  $\mu$ M all-trans retinoic acid (ATRA) to drive cells to a DC precursor phenotype. Cells were then cultured from day 9 to day 12 in the presence of GM-CSF and  
10 TNF- $\alpha$ , plus DMSO, Actimid<sup>TM</sup> or ATRA, to drive differentiation of the murine cells to immature dendritic cells. See Section 6.8 for details.

FIGS. 31(A-E). Murine cells present at day 9 under normal culture conditions (*see* Example 1, Materials & Methods; description of FIG. 30). Cells were labeled with antibodies to CD80 (FIG. 31A), CD11 (FIG. 31B), CD32/16 (FIG. 31C), MHC II (I-A<sup>b</sup>)  
15 (FIG. 31D), CD14 (FIG. 31E) or Gr-1 (FIG. 31F). Cells at day 9 exhibited labeling with to the CD88, CD11 and CD32/16 markers, little labeling with antibodies to the I-A<sup>b</sup> marker, and none to CD14 or Gr-1. See Section 6.8 for details.

FIGS. 32(A-I). Flow cytograms of day 12 murine cells treated with DMSO, Actimid<sup>TM</sup> or ATRA. Cells were labeled with antibodies to CD86 and CD11b. FIGS. 32A-  
20 32C (top row): cytograms showing percentages of cells expressing CD86 (Y-axis) when treated with DMSO (control), Actimid<sup>TM</sup> or all-trans retinoic acid (ATRA). FIGS. 32D-32F (middle row): percentage of cells expressing the major histocompatibility II (MHC II) marker; treatment as in top row. FIGS. 32G-32I (bottom row): percentage of cells expressing CD11b; treatment as in top row. See Section 6.8 for details.

## 25 5. DETAILED DESCRIPTION OF THE INVENTION

The present invention is based, in part, on the unexpected discovery that the exposure of stem cells or progenitor cells to the compounds of the invention results in a regulatable means of controlling the differentiation of stem or progenitor cells into specific populations of progenitor cells or differentiation of progenitor cells into specific cell types,  
30 such as dendritic cells, granulocytes, endothelial cells or neural cells. In particular, the exposure of stem or progenitor cells to the compounds of the invention results in the regulatable differentiation and expansion of specific populations of hematopoietic cells, including CD34+, CD38+ and CD133+ cells. Such regulation of differentiation is accomplished without significant loss of yield due to cell death or differentiation to

undesired cell types or cell lineages; in other words, the compounds of the invention do not cause apoptosis of one or more cell populations. Further, the exposure of hematopoietic progenitor cells to the compounds of the invention results in regulatable differentiation and expansion of specific cell types.

5 Thus, the present invention provides methods of modulating human stem cell differentiation, specifically CD34<sup>+</sup> hematopoietic progenitor cell, and CD133<sup>+</sup> progenitor cell differentiation. In particular, the present invention provides methods that employ small organic molecules that inhibit TNF- $\alpha$  activity to modulate the differentiation of progenitor cell populations along specific cell and tissue lineages. Further, the invention encompasses  
10 methods of expanding early progenitor cells, such as human CD133<sup>+</sup> or CD34<sup>+</sup>, particularly CD34<sup>+</sup>CD38<sup>-</sup> cells, for transplantation into mammals, birds or reptiles, comprising exposing hematopoietic progenitor cells to a TNF- $\alpha$  inhibitor or antagonist, wherein the inhibitor or antagonist is a small molecule. The invention also provides methods of producing other cell types from these early progenitor cells, including, but not limited to, cells of the brain,  
15 kidney, intestinal tract and muscle. The compounds of the invention also act to suppress dendritic cell differentiation, and promote granulocytic cell differentiation, from early progenitor cells, such as human CD34<sup>+</sup> progenitor cells.

Examples of the small molecule compounds that may be used in connection with the invention, include, but are not limited to, compounds that inhibit TNF- $\alpha$  activity.

20 Compounds that may be used in the methods of the invention are described in detail in Section 5.3. In one embodiment, the preferred compounds are thalidomide analogs, although thalidomide hydrolysis products, metabolites, derivatives and precursors of thalidomide may also be used. In particularly preferred embodiments, the compounds are IMiDs<sup>TM</sup> (Celgene) such as Actimid<sup>TM</sup> and Revimid<sup>TM</sup>.

25 The methods of the invention encompass the regulation of differentiation of a stem or progenitor cell into a specific cell lineage, including, but not limited to, a mesenchymal, hematopoietic, adipogenic, hepatogenic, neurogenic, gliogenic, chondrogenic, vasogenic, myogenic, chondrogenic, or osteogenic lineage comprising incubating the stem or progenitor cell with a compound of the invention, preferably *in vitro*, for a sufficient period of time to  
30 result in the differentiation of the cell into a cell of a desired cell lineage. In a specific embodiment, differentiation of a stem or progenitor cell into a cell of the hematopoietic lineage is modulated. In particular, the methods of the invention may be used to modulate the generation of blood cell colony generation from CD34<sup>+</sup>, CD133<sup>+</sup>, and CD45<sup>+</sup> hematopoietic progenitor cells in a dose-responsive manner.

The methods of the invention also encompass the regulation of differentiation of a CD34<sup>+</sup> progenitor cell into dendritic cells comprising incubating the progenitor cell with a compound of the invention, preferably *in vitro*, for a sufficient period of time to result in the differentiation of the cell into a cell of a desired cell lineage. In a specific embodiment, 5 differentiation of a such a progenitor cell into a cell of the dendritic cell lineage is modulated through contacting said cell with Actimid™ or Revimid™, or an analog or prodrug of either. In another specific embodiment, the differentiation of a CD34<sup>+</sup> progenitor cell is modulated to suppress differentiation along a myeloid lineage and encourage differentiation along a granulocytic lineage. In a more specific embodiment, 10 differentiation of a CD34<sup>+</sup> progenitor cell into a cell of a granulocytic cell lineage is modulated by a method comprising contacting a CD34<sup>+</sup> progenitor cell with a compound of the invention on the first day said progenitor cells are cultured.

Any mammalian stem or progenitor cell can be used in accordance with the methods of the invention, including but not limited to, stem cells isolated from cord blood ("CB" cells), 15 placenta and other sources. The stem cells may include pluripotent cells, *i.e.*, cells that have complete differentiation versatility, that are self-renewing, and can remain dormant or quiescent within tissue. The stem cells may also include multipotent cells or committed progenitor cells. In one preferred embodiment, the invention utilizes stem cells that are viable, quiescent, pluripotent stem cells that exist within the full-term placenta can be 20 recovered following successful birth and placental expulsion, exsanguination and perfusion resulting in the recovery of multipotent and pluripotent stem cells.

In another preferred embodiment, the progenitor cells are early progenitor cells, particularly CD34<sup>+</sup> or CD133<sup>+</sup> cells. Preferably, CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells are derived from human bone marrow, placenta, or cord blood. Equivalents of these cells from 25 other mammals may also be used. In mouse, for example, Sca<sup>+</sup> progenitor cells may be used in the methods of the invention. Equivalent early progenitor cells from birds or reptiles may also be used.

In a particular embodiment of the invention, cells endogenous to the placenta, or produced by a post-partum perfused placenta, including, but not limited to, embryonic-like 30 stem cells, progenitor cells, pluripotent cells and multipotent cells, are exposed to the compounds of the invention and induced to differentiate while being cultured in an isolated and perfused placenta. The endogenous cells propagated in the postpartum perfused placental may be collected, and/or bioactive molecules recovered from the perfusate, culture medium or from the placenta cells themselves.

In another embodiment of the invention, stem or progenitor cells that are derived from sources other than postpartum placenta are exposed to the compounds of the invention and induced to differentiate while being cultured *in vitro*. Thus, the invention encompasses methods for differentiating mammalian stem cells into specific progenitor cells comprising 5 differentiating the stem cells under conditions and/or media suitable for the desired differentiation and in the presence of a compound of the invention.

Further, the invention encompasses methods for modulating or regulating the differentiation of a population of a specific progenitor cell into specific cell types comprising differentiating said progenitor cell under conditions suitable for said 10 differentiation and in the presence of one or more compounds of the invention.

Alternatively, the stem or progenitor cell can be exposed to a compound of the invention and subsequently differentiated using suitable conditions. Examples of suitable conditions include nutrient media formulations supplemented with human serum and cell culture matrices, such as MATRIGEL® supplemented with growth factors.

15 The method of the invention also contemplates that different cell populations may be produced by contacting the progenitor cell(s) with a compound of the invention at various times during culture, either at the proliferation or differentiation stage. See Section 5.4, particularly Section 5.4.2, below.

20 In a specific embodiment, the present invention provides methods that employ amides and imide small molecules, particularly amino conjugates of thalidomide, to modulate and regulate hematopoiesis in the context of pre-transplantation conditioning of hematopoietic progenitors.

The present invention also provides methods that employ the small molecules of the invention to modulate and regulate hematopoiesis in the context of *ex vivo* conditioning of 25 hematopoietic progenitors. The methods of the invention encompass the regulation of stem or progenitor cell differentiation *in vitro*, comprising incubating the stem or progenitor cells with the compound *in vitro*, followed by direct transplantation of the differentiated cells to a subject.

The invention also encompasses the control or regulation of stem or progenitor cells 30 *in vivo* by the administration of both a stem or progenitor cell and a compound of the invention to a patient in need thereof.

The invention further encompasses the transplantation of pretreated stem or progenitor cells to treat or prevent disease. In one embodiment, a patient in need of transplantation is also administered a compound of the invention before, during and/or after 35 transplantation. In another embodiment, a patient in need of transplantation is also

administered untreated stem or progenitor cells, *e.g.*, cord blood cells, adult blood cells, peripheral blood cells, or bone marrow cells. In another embodiment, the methods of the invention include the administration of the compounds to a subject that is the recipient of unconditioned stem cells or progenitor cells for the purpose of eliciting a modulatory effect 5 on the stem cells that have already been transplanted.

In certain embodiments, the invention encompasses bone marrow transplantation which comprises transplanting cord blood (or stem cells obtained from cord blood), peripheral (*i.e.*, adult) blood (or stem cells obtained from peripheral blood), wherein said cord blood or stem cells have been pretreated with a compound of the invention. Further, the 10 invention encompasses the use of white blood cells made from hematopoietic progenitor cells that have been differentiated in the presence of a compound of the invention. For example, white blood cells produced by differentiating hematopoietic progenitor can be used in transplantation or can be mixed with cord blood or cord blood stem cells prior to transplantation.

15 In other embodiments, the invention encompasses bone marrow transplantation which comprises transplanting early progenitor cells, such as CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells, obtained according to the methods of the invention, wherein said progenitor cells have been pretreated with a compound of the invention. In one embodiment of the invention, said dendritic cell precursors are CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> precursor 20 cells. Further, the invention encompasses the use of cells made from CD34<sup>+</sup> progenitor cells that have been differentiated in the presence of a compound of the invention. For example, CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> precursor cells, CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> precursor cells, granulocytes, etc. produced by the differentiation of CD34<sup>+</sup> progenitor cells using the 25 compounds of the invention can be used in transplantation. Cells differentiated from CD133<sup>+</sup> cells, using the compounds of the invention, are also encompassed by the present invention.

The invention further encompasses methods of conditioning stem cells following cryopreservation and thawing, to counteract the deleterious effects of cryopreservation and exposure to cryopreservatives on the stem cells. In certain embodiments, the invention 30 provides methods of conditioning stem cells following cryopreservation and thawing, to counteract the deleterious effects of exposure to cryopreservatives (*e.g.*, DMSO) on the proliferative and migratory capacity of stem cells.

## 5.1. MODULATION OF DIFFERENTIATION OF STEM CELLS AND CD34+ OR CD133+ PROGENITOR CELLS

### 5.1.1. Stem Cells

The present invention provides methods of modulating human stem cell differentiation. In certain embodiments, the methods of the invention encompass the regulation of stem or progenitor cell differentiation *in vitro*, comprising incubating the stem cells with the compound *in vitro*, followed by direct transplantation of the differentiated cells to a subject. In other embodiments, the methods of the invention encompass the regulation of stem or progenitor cell differentiation *in vivo*, comprising delivering the compounds to a subject that is the recipient of unconditioned stem cells, followed by direct administration of the compound to the subject.

The embryonic-like stem cells obtained by the methods of the invention may be induced to differentiate along specific cell lineages, including, but not limited to a mesenchymal, hematopoietic, adipogenic, hepatogenic, neurogenic, gliogenic, chondrogenic, vasogenic, myogenic, chondrogenic, or osteogenic lineage.

In certain embodiments, embryonic-like stem cells obtained according to the methods of the invention are induced to differentiate for use in transplantation and ex vivo treatment protocols. In certain embodiments, embryonic-like stem cells obtained by the methods of the invention are induced to differentiate into a particular cell type and genetically engineered to provide a therapeutic gene product. In a specific embodiment, embryonic-like stem cells obtained by the methods of the invention are incubated with a compound, such as a small organic molecule, *in vitro*, that induces it to differentiate, followed by direct transplantation of the differentiated cells to a subject. In a preferred embodiment, the compounds that are used to control or regulate differentiation of stem cells are not polypeptides, peptides, proteins, hormones, cytokines, oligonucleotides or nucleic acids.

Stem cells that may be used in accordance with the invention include, but are not limited to, cord blood (CB) cells, placental cells, embryonic stem (ES) cells, embryonic-like stem cells, trophoblast stem cells, progenitor cells, bone marrow stem cells and multipotent, pluripotent and totipotent cells.

In particular, the methods of the invention encompass the regulation of the differentiation of stem cell populations, in addition to mesenchymal stem cells, into specific tissue lineages. For example, the methods of the invention may be employed to regulate the differentiation of a multipotent stem cell into chondrogenic, vasogenic, myogenic, and osteogenic lineage cells by promoting specific musculoskeletal regeneration and repair, neoangiogenesis, and repopulation of specific muscular tissues, such as myocardium and

skeletal muscle, and revascularization of a variety of organs and tissues including, but not limited to brain, spinal cord, liver, lung, kidney and pancreas. The methods of the invention may be employed to regulate differentiation of a multipotent stem cell into cell of adipogenic, chondrogenic, osteogenic, neurogenic or hepatogenic lineage.

5       The agent used to modulate differentiation can be introduced into the postpartum perfused placenta to induce differentiation of the cells being cultured in the placenta. Alternatively, the agent can be used to modulate differentiation *in vitro* after the cells have been collected or removed from the placenta.

10      The methods of the invention encompass the regulation of progenitor stem cell differentiation to a cell of the hematopoietic lineage, comprising incubating the progenitor stem cells with the compound *in vitro* for a sufficient period of time to result in the differentiation of these cells to a hematopoietic lineage. In particular, the methods of the invention may be used to modulate the generation of blood cell colony generation from CD34+, CD133+, and CD45+ hematopoietic progenitor cells in a dose-responsive manner (for discussion 15 of dosing, see Section 5.7).

Preferably, the methods of the invention may be used to suppress specifically the generation of red blood cells or erythropoietic colonies (BFU-E and CFU-E), while augmenting both the generation of leukocyte and platelet forming colonies (CFU-GM) and enhancing total colony forming unit production. The methods of the invention may be used 20 not only to regulate the differentiation of stem cells, but may also be used to stimulate the rate of colony formation, providing significant benefits to hematopoietic stem cell transplantation by improving the speed of bone marrow engraftment and recovery of leukocyte and/or platelet production.

In other embodiments, the methods of the invention may be used to regulate the 25 differentiation of *e.g.*, a neuronal precursor cell or neuroblast into a specific neuronal cell type such as a sensory neuron (*e.g.*, a retinal cell, an olfactory cell, a mechanosensory neuron, a chemosensory neuron, etc.), a motor neuron, a cortical neuron, or an interneuron. In other embodiments, the methods of the invention may be used to regulate the differentiation of cell 30 types including, but not limited to, cholinergic neurons, dopaminergic neurons, GABA-ergic neurons, glial cells (including oligodendrocytes, which produce myelin), and ependymal cells (which line the brains ventricular system). In yet other embodiments, the methods of the invention may be used to regulate the differentiation of cells that are constituent of organs, including, but not limited to, purkinje cells of the heart, biliary epithelium of the liver, beta-islet cells of the pancreas, renal cortical or medullary cells, and retinal photoreceptor cells of 35 the eye.

Assessment of the differentiation state of stem cells obtained according to the methods of the invention may be identified by the presence of cell surface markers. Embryonic-like stem cells of the invention, for example, may be distinguished by the following cell surface markers: OCT-4+ and ABC-pt. Further, the invention encompasses embryonic-like stem 5 cells having the following markers: CD10, CD29, CD44, CD54, CD90, SH2, SH3, SH4, OCT-4 and ABC-p, or lacking the following cell surface markers: CD34, CD38, CD45, SSEA3 and SSEA4, as described hereinabove. Such cell surface markers are routinely determined according to methods well known in the art, e.g. by flow cytometry, followed by washing and staining with an anti-cell surface marker antibody. For example, to determine 10 the presence of CD34 or CD38, cells maybe washed in PBS and then double-stained with anti-CD34 phycoerythrin and anti-CD38 fluorescein isothiocyanate (Becton Dickinson, Mountain View, CA).

### **5.1.2. CD34+ And CD133+ Early Progenitor Cells**

The present invention also provides methods of modulating human CD34<sup>+</sup> or 15 CD133<sup>+</sup> cell differentiation. In certain embodiments, the methods of the invention encompass the regulation of stem or progenitor cell differentiation *in vitro*, comprising incubating the stem cells with the compound *in vitro*, followed by direct transplantation of the differentiated cells to a subject.

The progenitor cells obtained by the methods of the invention may be induced to 20 differentiate along specific cell lineages, including, but not limited to, for CD34<sup>+</sup> progenitor cells, a myeloid or granulocytic, lineage, and for CD133<sup>+</sup> cells, an endothelial or neural cell lineage. In certain embodiments, progenitor cells are induced to differentiate for use in transplantation and *ex vivo* treatment protocols. In certain embodiments, progenitor cells are induced to differentiate into a particular cell type and genetically engineered to provide 25 a therapeutic gene product. In a specific embodiment, progenitor cells are incubated with a compound, such as a small organic molecule, *in vitro*, that induces it to differentiate, followed by direct transplantation of the differentiated cells to a subject. In a preferred embodiment, the compounds that are used to control or regulate differentiation of stem cells are not polypeptides, peptides, proteins, hormones, cytokines, oligonucleotides or nucleic 30 acids. In another preferred embodiment, the progenitor cell is caused to differentiate into a CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> progenitor cell.

Preferably, the methods of the invention may be used to suppress specifically the generation of red blood cells or erythropoietic colonies (BFU-E and CFU-E), while augmenting both the generation of leukocyte and platelet forming colonies (CFU-GM) and 35 enhancing total colony forming unit production. The methods of the invention may be used

not only to regulate the differentiation of stem cells, but may also be used to stimulate the rate of colony formation, providing significant benefits to hematopoietic stem cell transplantation by improving the speed of bone marrow engraftment and recovery of leukocyte and/or platelet production.

5 In other embodiments, the methods of the invention may be used to reduce the differentiation of CD34<sup>+</sup> progenitor cells into CD1a<sup>+</sup> cells, particularly CD86<sup>+</sup>CD1a<sup>+</sup> cells. In another embodiment, the methods of the invention may be used to reduce or prevent the differentiation of CD34<sup>+</sup> progenitor cells into CD14<sup>+</sup>CD1a<sup>-</sup> cells. CD14<sup>+</sup>CD1a<sup>-</sup> cells are dermal dendritic cell or monocyte/macrophage progenitor cells. In another embodiment, the  
10 methods of the invention may be used to reduce the expression on proliferating CD34<sup>+</sup> progenitor cells of co-stimulatory molecules CD80 and CD86. In another embodiment, the methods of the invention may be used to reduce the differentiation of proliferating CD34<sup>+</sup> progenitor cells into CD54<sup>bright</sup> cells, and to encourage differentiation into CD54<sup>dim</sup> cells. In another embodiment, the methods of the invention may be used to increase the number of  
15 CD133<sup>+</sup> cells, which are endothelial cell progenitor cells. In yet another embodiment, the methods of the invention may be used to decrease the differentiation of proliferating CD34<sup>+</sup> cells into CD11c<sup>-</sup>CD15<sup>+</sup> cells, and increase differentiation into CD11c<sup>+</sup>CD15<sup>-</sup> cells, thus shifting differentiation from a myeloid dendritic cell lineage to a granulocytic lineage.

Assessment of the differentiation state of stem cells obtained according to the  
20 methods of the invention may be identified by the presence of cell surface markers. Progenitor cells of the invention, for example, may be distinguished by the CD34<sup>+</sup> or CD133<sup>+</sup> cell surface markers. Further, the invention encompasses proliferating progenitor cells possessing, or showing increased expression relative to a control, of one or more of the following markers: CD15, CD34, CD33, CD133, or CD54<sup>dim</sup>, as described hereinabove.  
25 The invention further encompasses proliferating progenitor cells lacking, or showing reduced expression relative to a control, of one or more of the following markers: HLA-DR, CD1a, CD11c, CD38, CD80, CD86, CD54<sup>bright</sup> or CD14. In a preferred embodiment, proliferating progenitor cells of the invention exhibit CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup>. Such cell surface markers are routinely determined according to methods well known in the art, e.g. by washing and staining with an anti-cell surface marker antibody, followed by flow cytometry. For example, to determine the presence of CD34 or CD38, cells may be washed in PBS and then double-stained with anti-CD34 phycoerythrin and anti-CD38 fluorescein isothiocyanate (Becton Dickinson, Mountain View, CA).

In certain embodiment, differentiated cells may be characterized by characterizing  
35 the phagocytic capacity of the differentiated cells. The capacity of differentiated, or

differentiating, cells to phagocytose may be assessed by, for example, labeling dextran with FITC and determining the amount of uptake by known methods. The capacity of differentiated, or differentiating, cells to ability to stimulate T cells may be assessed in a mixed leukocyte reaction (MLR), in which presumptively antigen-loaded cells are mixed 5 with T cells, and the level of T cell activation is determined.

### **5.1.3. Identification and Characterization of Cells**

In certain embodiments, differentiated cells maybe identified by characterizing differentially expressed genes (for example, characterizing a pool of genes from an undifferentiated progenitor cell(s) of interest versus a pool of genes from a differentiated 10 cell derived from the progenitor cell). For example, nucleic acid amplification methods such as polymerase chain reaction (PCR) or transcription-based amplification methods (*e.g., in vitro* transcription (IVT)) may be used to profile gene expression in different populations of cells, *e.g.*, by use of a polynucleotide microarray. Such methods to profile differential gene expression are well known in the art (see; *e.g.*, Wieland *et al.*, Proc. Natl. Acad. Sci. USA 15 87: 2720-2724 (1990; Lisitsyn *et al.*, Science 259: 946-951 (1993); Lisitsyn *et al.*, Meth. Enzymology 254: 291-304 (1995); U.S. Pat. No. 5,436,142; U.S. Pat. No. 5,501,964; Lisitsyn *et al.*, Nature Genetics 6: 57-63 (1994); Hubank and Schatz, 1994, Nucleic Acids Research 22: 5640-5648; Zeng *et al.*, 1994, Nucleic Acids Research 22: 4381-4385; U.S. Pat. No. 5,525,471; Linsley *et al.*, U.S. Patent No. 6,271,002, entitled "RNA amplification method," 20 issued August 7, 2001; Van Gelder *et al.*, U.S. Pat. No. 5,716,785, entitled "Processes for genetic manipulations using promoters," issued Feb. 10, 1998; Stoflet *et al.*, 1988, Science 239:491-494, 1988; Sarkar and Sommer, 1989, Science 244: 331-334; Mullis *et al.*, U.S. Pat. No. 4,683,195; Malek *et al.*, U.S. Pat. No. 5,130,238; Kacian and Fultz, U.S. Pat. No. 5,399,491; Burg *et al.*, U.S. Pat. No. 5,437,990; R. N Van Gelder *et al.* (1990), Proc. Natl. Acad. Sci. USA 87, 1663; D. J. Lockhart *et al.*, 1996, Nature Biotechnol. 14, 1675; Shannon, 25 U.S. Patent No. 6,132,997; Lindemann *et al.*, U.S. Patent No. 6,235,503, entitled "Procedure for subtractive hybridization and difference analysis," issued May 22, 2001).

Commercially available kits are available for gene profiling, *e.g.*, the displayPROFILE™ series of kits (Qbiogene, Carlsbad, CA, which uses a gel- based approach 30 for profiling gene expression. The kits utilize Restriction Fragment Differential Display-PCR (RFDD-PCR) to compare gene expression patterns in eukaryotic cells. A PCR-Select Subtraction Kit (Clontech) and a PCR-Select Differential Screening Kit (Clontech) may also be used, which permits identification of differentially expressed clones in a subtracted library. After generating pools of differentially expressed genes with the PCR-Select Subtraction kit, 35 the PCR-Select Differential Screening kit is used. The subtracted library is hybridized with

probes synthesized directly from tester and driver populations, a probe made from the subtracted cDNA, and a probe made from reverse-subtracted cDNA (a second subtraction performed in reverse). Clones that hybridize to tester but not driver probes are differentially expressed; however, non-subtracted probes are not sensitive enough to detect rare messages.

- 5 Subtracted probes are greatly enriched for differentially expressed cDNAs, but may give false positive results. Using both subtracted and non-subtracted probes according to the manufacturer's (Clontech) instructions identifies differentially expressed genes.

In another embodiment, differentiated stem or progenitor cells are identified and characterized by a colony forming unit assay, which is commonly known in the art, such as  
10 Mesen Cult™ medium (Stem Cell Technologies, Inc., Vancouver British Columbia).

Determination that a stem cell or progenitor has differentiated into a particular cell type may be accomplished by methods well-known in the art, *e.g.*, measuring changes in morphology and cell surface markers using techniques such as flow cytometry or immunocytochemistry (*e.g.*, staining cells with tissue-specific or cell-marker specific antibodies), by examination of the morphology of cells using light or confocal microscopy, or by measuring changes in gene expression using techniques well known in the art, such as PCR and gene-expression profiling.  
15

## 5.2. STEM AND PROGENITOR CELL POPULATIONS

The present invention provides methods of modulating human stem cell differentiation. Any mammalian stem cell can be used within the methods of the invention, including, but not limited to, stem cells isolated from cord blood (CB cells), peripheral blood, adult blood, bone marrow, placenta, mesenchymal stem cells and other sources. In a non-preferred embodiment, the stem cells are embryonic stem cells or cells that have been isolated from sources other than placenta.  
25

Sources of mesenchymal stem cells include bone marrow, embryonic yolk sac, placenta, umbilical cord, fetal and adolescent skin, and blood. Bone marrow cells may be obtained, for example, from iliac crest, femora, tibiae, spine, rib or other medullary spaces.

The stem cells to be used in accordance with the methods of the present invention may include pluripotent cells, *i.e.*, cells that have complete differentiation versatility, that are self-renewing, and can remain dormant or quiescent within tissue. The stem cells may also include multipotent cells, committed progenitor cells, and fibroblastoid cells. In one preferred embodiment, the invention utilizes stem cells that are viable, quiescent, pluripotent stem cells isolated from a full-term exsanguinated perfused placenta.  
30

Stem cell populations may consist of placental stem cells obtained through a commercial service, *e.g.*. LifeBank USA (Cedar Knolls, NJ), ViaCord (Boston MA), Cord Blood Registry (San Bruno, CA) and Cryocell (Clearwater, FL).

Stem cell populations may also consist of placental stem cells collected according to 5 the methods disclosed in U.S. Application Publication No. US 20020123141, published September 5, 2002, entitled "Method of Collecting Placental Stem Cells" and U.S. Application Publication No. US 20030032179, published February 13, 2003, entitled "Post-Partum Mammalian Placenta, Its Use and Placental Stem Cells Therefrom" (both of which are incorporated herein by reference in their entireties).

10 In one embodiment, stem cells from cord blood may be used. The first collection of blood from the placenta is referred to as cord blood, which contains predominantly CD34<sup>+</sup> and CD38<sup>+</sup> hematopoietic progenitor cells. Within the first twenty-four hours of postpartum perfusion, high concentrations of CD34<sup>+</sup>CD38<sup>-</sup> hematopoietic progenitor cells may be isolated from the placenta. After about twenty-four hours of perfusion, high concentrations 15 of CD34<sup>-</sup>CD38<sup>-</sup> cells can be isolated from the placenta along with the aforementioned cells. The isolated perfused placenta of the invention provides a source of large quantities of stem cells enriched for CD34<sup>+</sup>CD38<sup>-</sup> stem cells and CD34<sup>-</sup>CD38<sup>+</sup> stem cells: The isolated placenta that has been perfused for twenty-four hours or more provides a source of large quantities of stem cells enriched for CD34<sup>-</sup> and CD38<sup>-</sup> stem cells.

20 Preferred cells to be used in accordance with the present invention are embryonic-like stem cells that originate from an exsanguinated perfused placenta, or cells that derive from embryonic-like placental stem cells. The embryonic-like stem cells off the invention may be characterized by measuring changes in morphology and cell surface markers using techniques such as flow cytometry and immunocytochemistry, and measuring changes in gene expression 25 using techniques, such as PCR. In one embodiment of the invention, such embryonic-like stem cells may be characterized by the presence of the following cell surface markers: CD10, CD29, CD44, CD54, CD90, SH2, SH3, SH4, OCT-4 and ABC-p, or the absence of the following cell surface markers: CD34, CD38, CD45, SSEA3 and SSEA4. In a preferred embodiment, such embryonic-like stem cells may be characterized by the presence of cell 30 surface markers OCT-4 and APC-p. Such cell surface markers are routinely determined according to methods well known in the art, *e.g.* by flow cytometry, followed by washing and staining with an anti-cell surface marker antibody. For example, to determine the presence of CD34 or CD38, cells may be washed in PBS and then double-stained with anti-CD34 phycoerythrin and anti-CD38 fluorescein isothiocyanate (Becton Dickinson, Mountain 35 View, CA).

Embryonic-like stem cells originating from placenta have characteristics of embryonic stem cells but are not derived from the embryo. In other words, the invention encompasses the use of OCT-4+ and ABC-p+ cells that are undifferentiated stem cells that are isolated from a postpartum perfused placenta. Such cells are as versatile (*e.g.*, 5 pluripotent) as human embryonic stem cells. As mentioned above, a number of different pluripotent or multipotent stem cells can be isolated from the perfused placenta at different time points *e.g.*, CD34+ CD38+, CD34+ CD38-, and CD34-CD38- hematopoietic cells. According to the methods of the invention, human placenta is used post-birth as the source of embryonic-like stem cells.

10 For example, after expulsion from the womb, the placenta is exsanguinated as quickly as possible to prevent or minimize apoptosis. Subsequently, as soon as possible after exsanguination the placenta is perfused to remove blood, residual cells, proteins, factors and any other materials present in the organ. Materials debris may also be removed from the placenta. Perfusion is normally continued with an appropriate perfusate for at least two to 15 more than twenty-four hours. In several additional embodiments the placenta is perfused for at least 4, 6, 8, 10, 12, 14, 16, 18, 20, and 22 hours. In other words, this invention is based at least in part on the discovery that the cells of a postpartum placenta can be activated by exsanguination and perfusion for a sufficient amount of time. Therefore, the placenta can readily be used as a rich and abundant source of embryonic-like stem cells, which cells can be 20 used for research, including drug discovery, treatment and prevention of diseases, in particular transplantation surgeries or therapies, and the generation of committed cells, tissues and organoids. *See* co-pending Application Ser. No. 10/004,942, filed December 5, 2001 entitled "Method of Collecting Placental Stem Cells" and Application Ser. No. 10/076,180, filed February 13, 2002, entitled "Post-Partum Mammalian Placenta, Its Use and Placental 25 Stem Cells Therefrom," both of which are incorporated herein by reference in their entireties.

Embryonic-like stem cells are extracted from a drained placenta by means of a perfusion technique that utilizes either or both of the umbilical artery and umbilical vein. The placenta is preferably drained by exsanguination and collection of residual blood (*e.g.*, residual umbilical cord blood). The drained placenta is then processed in such a manner as 30 to establish an *ex vivo*, natural, bioreactor environment in which resident embryonic-like stem cells within the parenchyma and extravascular space are recruited. The embryonic-like stem cells migrate into the drained, empty microcirculation where, according to the methods of the invention, they are collected, preferably by washing into a collecting vessel by perfusion.

Specifically contemplated as part of the invention is the modulation of CD34<sup>+</sup> and CD133<sup>+</sup> progenitor cells into myeloid cells, particularly dendritic or granulocytic cells. Recent reports indicate that such cells are pluripotent; thus, the invention also contemplates the modulation of the development of these progenitor into cells of the brain, kidney, 5 intestinal tract, liver or muscle.

Any mammalian, avian or reptilian CD34<sup>+</sup> or CD133<sup>+</sup> stem or progenitor cell can be used within the methods of the invention, including, but not limited to, stem cells isolated from cord blood (CB cells), peripheral blood, adult blood, bone marrow, placenta, including perfused placenta (see U.S. Application Publication No. US 20030032179, 10 published February 13, 2003, entitled "Post-Partum Mammalian Placenta, Its Use and Placental Stem Cells Therefrom", which is incorporated herein by reference in its entirety), mesenchymal stem cells and other sources. In a preferred embodiment, the stem cells are hematopoietic stem cells or cells that have been isolated from bone marrow. Such cells may be obtained from other organs or tissues, but such sources are less preferred.

15 In one embodiment, progenitor cells from cord blood or from post-partum placenta may be used. As noted above, cord blood contains predominantly CD34+ and CD38+ hematopoietic progenitor cells. Within the first twenty-four hours of postpartum perfusion, high concentrations of CD34+ CD38- hematopoietic progenitor cells may be isolated from an isolated, perfused placenta. After about twenty-four hours of perfusion, high 20 concentrations of CD34- CD38- cells can be isolated from the placenta along with the aforementioned cells. In another embodiment, progenitor cell populations may be obtained through a commercial service, e.g., LifeBank USA (Cedar Knolls, NJ), ViaCord (Boston MA), Cord Blood Registry (San Bruno, CA) and Cryocell (Clearwater, FL).

### 5.3. THE COMPOUNDS OF THE INVENTION

25 Compounds used in the invention are referred to herein as "immunomodulatory compounds," and include immunomodulatory compounds that are racemic, stereomerically enriched or stereomerically pure and pharmaceutically acceptable salts, solvates, hydrates, stereoisomers, clathrates, and prodrugs thereof. Preferred compounds used in the invention are small organic molecules having a molecular weight less than about 1000 g/mol, and are 30 not proteins, peptides, oligonucleotides, oligosaccharides or other macromolecules.

As used herein and unless otherwise indicated, the term "stereomerically pure" means a composition that comprises one stereoisomer of a compound and is substantially free of other stereoisomers of that compound. For example, a stereomerically pure composition of a compound having one chiral center will be substantially free of the 35 opposite enantiomer of the compound. A stereomerically pure composition of a compound

having two chiral centers will be substantially free of other diastereomers of the compound. As used herein and unless otherwise indicated, the term "enantiomerically pure" means a stereomerically pure composition of a compound having one chiral center. As used herein and unless otherwise indicated, the term "stereomerically enriched" means a composition 5 that comprises greater than about 60% by weight of one stereoisomer of a compound, preferably greater than about 70% by weight, more preferably greater than about 80% by weight of one stereoisomer of a compound. As used herein, the term "enantiomerically pure" means a stereomerically pure composition of a compound having one chiral center. Similarly, the term "enantiomerically enriched" means a stereomerically enriched 10 composition of a compound having one chiral center.

As used herein and unless otherwise indicated, the term "immunomodulatory compounds" or "IMIDs™" (Celgene Corporation) used herein encompasses small organic molecules that markedly inhibit TNF- $\alpha$ , LPS induced monocyte IL1 $\beta$  and IL12, and partially inhibit IL6 production. Specific immunomodulatory compounds of the invention 15 are discussed below. These compounds can be obtained commercially from, for example, Celgene, or prepared in accordance with the methods described in the patents or publications listed herein.

TNF- $\alpha$  is an inflammatory cytokine produced by macrophages and monocytes during acute inflammation. TNF- $\alpha$  is responsible for a diverse range of signaling events 20 within cells. TNF- $\alpha$  may play a pathological role in cancer. Without being limited by particular theory, one of the biological effects exerted by the immunomodulatory compounds of the invention is the reduction of synthesis of TNF- $\alpha$ . Immunomodulatory compounds of the invention enhance the degradation of TNF- $\alpha$  mRNA.

Further, without being limited by particular theory, immunomodulatory compounds 25 used in the invention may also be potent co-stimulators of T cells and increase cell proliferation dramatically in a dose dependent manner. Immunomodulatory compounds of the invention may also have a greater co-stimulatory effect on the CD8+ T cell subset than on the CD4+ T cell subset. In addition, the compounds preferably have anti-inflammatory properties, and efficiently co-stimulate T cells.

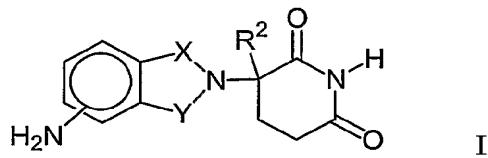

Specific examples of immunomodulatory compounds of the invention, include, but 30 are not limited to, cyano and carboxy derivatives of substituted styrenes such as those disclosed in U.S. patent no. 5,929,117; 1-oxo-2-(2,6-dioxo-3-fluoropiperidin-3-yl) isoindolines and 1,3-dioxo-2-(2,6-dioxo-3-fluoropiperidine-3-yl) isoindolines such as those described in U.S. patent no. 5,874,448; the tetra substituted 2-(2,6-dioxopiperidin-3-yl)-1-oxoisoindolines described in U.S. patent no. 5,798,368; 1-oxo and 1,3-dioxo-2-(2,6-

dioxopiperidin-3-yl) isoindolines (*e.g.*, 4-methyl derivatives of thalidomide and EM-12), including, but not limited to, those disclosed in U.S. patent no. 5,635,517; and a class of non-polypeptide cyclic amides disclosed in U.S. patent nos. 5,698,579 and 5,877,200. The entirety of each of the patents identified herein are incorporated herein by reference.

5    Immunomodulatory compounds of the invention do not include thalidomide.

Other specific immunomodulatory compounds of the invention include, but are not limited to, 1-oxo-and 1,3 dioxo-2-(2,6-dioxopiperidin-3-yl) isoindolines substituted with amino or substituted amino in the benzo ring as described in U.S. Patent no. 5,635,517 which is incorporated herein. These compounds have the structure I:

10

in which one of X and Y is C=O, the other of X and Y is C=O or CH<sub>2</sub>, and R<sup>2</sup> is hydrogen or lower alkyl, in particular methyl. Specific immunomodulatory compounds include, but are not limited to:

15

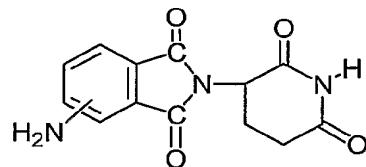

- 1-oxo-2-(2,6-dioxopiperidin-3-yl)-4-aminoisoindoline;
- 1-oxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline;
- 1-oxo-2-(2,6-dioxopiperidin-3-yl)-6-aminoisoindoline;
- 1-oxo-2-(2,6-dioxopiperidin-3-yl)-7-aminoisoindoline;
- 1,3-dioxo-2-(2,6-dioxopiperidin-3-yl)-4-aminoisoindoline;
- and 1,3-dioxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline.

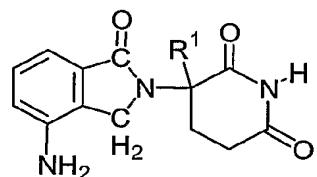

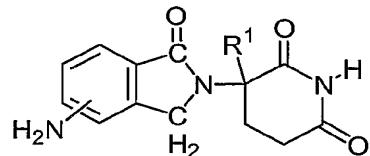

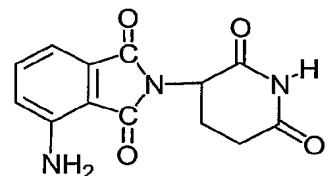

20

Other specific immunomodulatory compounds of the invention belong to a class of substituted 2-(2,6-dioxopiperidin-3-yl) phthalimides and substituted 2-(2,6-dioxopiperidin-3-yl)-1-oxoisooindoles, such as those described in U.S. patent nos. 6,281,230; 6,316,471; 6,335,349; and 6,476,052, and International Patent Application No. PCT/US97/13375 (International Publication No. WO 98/03502), each of which is incorporated herein.

25

Compounds representative of this class are of the formulas:

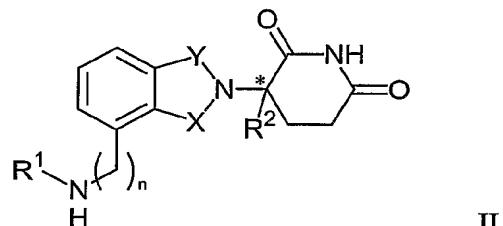

wherein R<sup>1</sup> is hydrogen or methyl. In a separate embodiment, the invention encompasses the use of enantiomerically pure forms (e.g. optically pure (R) or (S) enantiomers) of these compounds.

Still other specific immunomodulatory compounds of the invention belong to a class of isoindole-imides disclosed in U.S. patent application nos. 10/032,286 and 09/972,487, and International Application No. PCT/US01/50401 (International Publication No. WO 02/059106), each of which are incorporated herein by reference. Representative compounds are of formula II:

10

II

and pharmaceutically acceptable salts, hydrates, solvates, clathrates, enantiomers, diastereomers, racemates, and mixtures of stereoisomers thereof, wherein:

one of X and Y is C=O and the other is CH<sub>2</sub> or C=O;

R<sup>1</sup> is H, (C<sub>1</sub>-C<sub>8</sub>)alkyl, (C<sub>3</sub>-C<sub>7</sub>)cycloalkyl, (C<sub>2</sub>-C<sub>8</sub>)alkenyl, (C<sub>2</sub>-C<sub>8</sub>)alkynyl, benzyl, 15 aryl, (C<sub>0</sub>-C<sub>4</sub>)alkyl-(C<sub>1</sub>-C<sub>6</sub>)heterocycloalkyl, (C<sub>0</sub>-C<sub>4</sub>)alkyl-(C<sub>2</sub>-C<sub>5</sub>)heteroaryl, C(O)R<sup>3</sup>, C(S)R<sup>3</sup>, C(O)OR<sup>4</sup>, (C<sub>1</sub>-C<sub>8</sub>)alkyl-N(R<sup>6</sup>)<sub>2</sub>, (C<sub>1</sub>-C<sub>8</sub>)alkyl-OR<sup>5</sup>, (C<sub>1</sub>-C<sub>8</sub>)alkyl-C(O)OR<sup>5</sup>, C(O)NHR<sup>3</sup>, C(S)NHR<sup>3</sup>, C(O)NR<sup>3</sup>R<sup>3'</sup>, C(S)NR<sup>3</sup>R<sup>3'</sup> or (C<sub>1</sub>-C<sub>8</sub>)alkyl-O(CO)R<sup>5</sup>;

R<sup>2</sup> is H, F, benzyl, (C<sub>1</sub>-C<sub>8</sub>)alkyl, (C<sub>2</sub>-C<sub>8</sub>)alkenyl, or (C<sub>2</sub>-C<sub>8</sub>)alkynyl;

$R^3$  and  $R^{3'}$  are independently  $(C_1-C_8)alkyl$ ,  $(C_3-C_7)cycloalkyl$ ,  $(C_2-C_8)alkenyl$ ,  $(C_2-C_8)alkynyl$ , benzyl, aryl,  $(C_0-C_4)alkyl-(C_1-C_6)heterocycloalkyl$ ,  $(C_0-C_4)alkyl-(C_2-C_5)heteroaryl$ ,  $(C_0-C_8)alkyl-N(R^6)_2$ ,  $(C_1-C_8)alkyl-OR^5$ ,  $(C_1-C_8)alkyl-C(O)OR^5$ ,  $(C_1-C_8)alkyl-O(CO)R^5$ , or  $C(O)OR^5$ ;

- 5         $R^4$  is  $(C_1-C_8)alkyl$ ,  $(C_2-C_8)alkenyl$ ,  $(C_2-C_8)alkynyl$ ,  $(C_1-C_4)alkyl-OR^5$ , benzyl, aryl,  $(C_0-C_4)alkyl-(C_1-C_6)heterocycloalkyl$ , or  $(C_0-C_4)alkyl-(C_2-C_5)heteroaryl$ ;  
            $R^5$  is  $(C_1-C_8)alkyl$ ,  $(C_2-C_8)alkenyl$ ,  $(C_2-C_8)alkynyl$ , benzyl, aryl, or  $(C_2-C_5)heteroaryl$ ;

- 10      each occurrence of  $R^6$  is independently H,  $(C_1-C_8)alkyl$ ,  $(C_2-C_8)alkenyl$ ,  $(C_2-C_8)alkynyl$ , benzyl, aryl,  $(C_2-C_5)heteroaryl$ , or  $(C_0-C_8)alkyl-C(O)O-R^5$  or the  $R^6$  groups can join to form a heterocycloalkyl group;

n is 0 or 1; and

\* represents a chiral-carbon center.

- In specific compounds of formula II, when n is 0 then  $R^1$  is  $(C_3-C_7)cycloalkyl$ ,  $(C_2-C_8)alkenyl$ ,  $(C_2-C_8)alkynyl$ , benzyl, aryl,  $(C_0-C_4)alkyl-(C_1-C_6)heterocycloalkyl$ ,  $(C_0-C_4)alkyl-(C_2-C_5)heteroaryl$ ,  $C(O)R^3$ ,  $C(O)OR^4$ ,  $(C_1-C_8)alkyl-N(R^6)_2$ ,  $(C_1-C_8)alkyl-OR^5$ ,  $(C_1-C_8)alkyl-C(O)OR^5$ ,  $C(S)NHR^3$ , or  $(C_1-C_8)alkyl-O(CO)R^5$ ;

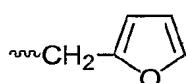

$R^2$  is H or  $(C_1-C_8)alkyl$ ; and

- $R^3$  is  $(C_1-C_8)alkyl$ ,  $(C_3-C_7)cycloalkyl$ ,  $(C_2-C_8)alkenyl$ ,  $(C_2-C_8)alkynyl$ , benzyl, aryl,  $(C_0-C_4)alkyl-(C_1-C_6)heterocycloalkyl$ ,  $(C_0-C_4)alkyl-(C_2-C_5)heteroaryl$ ,  $(C_5-C_8)alkyl-N(R^6)_2$ ;  $(C_0-C_8)alkyl-NH-C(O)O-R^5$ ;  $(C_1-C_8)alkyl-OR^5$ ,  $(C_1-C_8)alkyl-C(O)OR^5$ ,  $(C_1-C_8)alkyl-O(CO)R^5$ , or  $C(O)OR^5$ ; and the other variables have the same definitions.

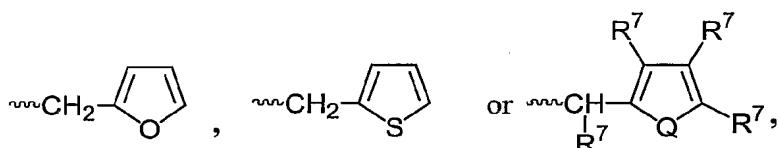

In other specific compounds of formula II,  $R^2$  is H or  $(C_1-C_4)alkyl$ .

In other specific compounds of formula II,  $R^1$  is  $(C_1-C_8)alkyl$  or benzyl.

- 25      In other specific compounds of formula II,  $R^1$  is H,  $(C_1-C_8)alkyl$ , benzyl,  $CH_2OCH_3$ ,  $CH_2CH_2OCH_3$ , or

In another embodiment of the compounds of formula II,  $R^1$  is

- 30      wherein Q is O or S, and each occurrence of  $R^7$  is independently H,  $(C_1-C_8)alkyl$ , benzyl,  $CH_2OCH_3$ , or  $CH_2CH_2OCH_3$ .

In other specific compounds of formula II,  $R^1$  is  $C(O)R^3$ .

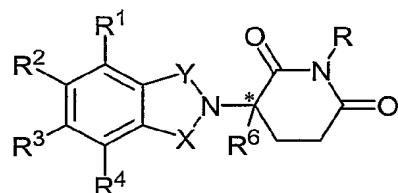

In other specific compounds of formula II, R<sup>3</sup> is (C<sub>0</sub>-C<sub>4</sub>)alkyl-(C<sub>2</sub>-C<sub>5</sub>)heteroaryl, (C<sub>1</sub>-C<sub>8</sub>)alkyl, aryl, or (C<sub>0</sub>-C<sub>4</sub>)alkyl-OR<sup>5</sup>.

In other specific compounds of formula II, heteroaryl is pyridyl, furyl, or thieryl.

In other specific compounds of formula II, R<sup>1</sup> is C(O)OR<sup>4</sup>.

5 In other specific compounds of formula II, the H of C(O)NHC(O) can be replaced with (C<sub>1</sub>-C<sub>4</sub>)alkyl, aryl, or benzyl.

Still other specific immunomodulatory compounds of the invention belong to a class of isoindole-imides disclosed in U.S. patent application no. 09/781,179, International Publication No. WO 98/54170, and United States Patent No. 6,395,754, each of which are 10 incorporated herein by reference. Representative compounds are of formula III:

III

and pharmaceutically acceptable salts, hydrates, solvates, clathrates, enantiomers, diastereomers, racemates, and mixtures of stereoisomers thereof, wherein:

one of X and Y is C=O and the other is CH<sub>2</sub> or C=O;

15 R is H or CH<sub>2</sub>OCCR';

(i) each of R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup>, or R<sup>4</sup>, independently of the others, is halo, alkyl of 1 to 4 carbon atoms, or alkoxy of 1 to 4 carbon atoms or (ii) one of R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup>, or R<sup>4</sup> is nitro or -NHR<sup>5</sup> and the remaining of R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup>, or R<sup>4</sup> are hydrogen;

R<sup>5</sup> is hydrogen or alkyl of 1 to 8 carbons

20 R<sup>6</sup> hydrogen, alkyl of 1 to 8 carbon atoms, benzo, chloro, or fluoro;

R' is R<sup>7</sup>-CHR<sup>10</sup>-N(R<sup>8</sup>R<sup>9</sup>);

R<sup>7</sup> is m-phenylene or p-phenylene or -(C<sub>n</sub>H<sub>2n</sub>)- in which n has a value of 0 to 4;

each of R<sup>8</sup> and R<sup>9</sup> taken independently of the other is hydrogen or alkyl of 1 to 8 carbon atoms, or R<sup>8</sup> and R<sup>9</sup> taken together are tetramethylene, pentamethylene,

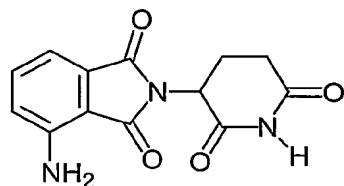

25 hexamethylene, or -CH<sub>2</sub>CH<sub>2</sub>[X]X<sub>1</sub>CH<sub>2</sub>CH<sub>2</sub>- in which [X]X<sub>1</sub> is -O-, -S-, or -NH-;

R<sup>10</sup> is hydrogen, alkyl of 1 to 8 carbon atoms, or phenyl; and

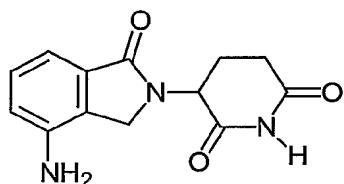

\* represents a chiral-carbon center.

The most preferred immunomodulatory compounds of the invention are 4-(amino)-2-(2,6-dioxo(3-piperidyl))-isoindoline-1,3-dione and 3-(4-amino-1-oxo-1,3-dihydro-30 isoindol-2-yl)-piperidine-2,6-dione. The compounds can be obtained via standard, synthetic methods (see e.g., United States Patent No. 5,635,517, incorporated herein by reference). The compounds are available from Celgene Corporation, Warren, NJ. 4-(Amino)-2-(2,6-

dioxo(3-piperidyl))-isoindoline-1,3-dione (ACTIMID<sup>TM</sup>) has the following chemical structure:

3-(4-amino-1-oxo-1,3-dihydro-isoindol-2-yl)-piperidine-2,6-dione (REVIMID<sup>TM</sup>) has the following chemical structure:

#### 5      5.4. METHODS OF STEM CELL CULTURE

In certain embodiments of the invention, stem or progenitor cells, including but not limited to embryonic stem cells, embryonic-like stem cells, progenitor cells, pluripotent cells, totipotent cells, multipotent cells, cells endogenous to a postpartum perfused placenta, cord blood cells, stem or progenitor cells derived from peripheral blood or adult blood, or bone marrow cells, are exposed to the compounds of the invention and induced to differentiate. These cells may be propagated *in vitro* using methods well known in the art, or alternatively, may be propagated in a postpartum perfused placenta.

In certain embodiments, cells endogenous to a postpartum perfused placenta may be collected from the placenta and culture medium and cultured *in vitro* under conditions appropriate, and for a time sufficient, to induce differentiation to the desired cell type or lineage. See U.S. Application Publication No. US 20030032179, published February 13, 2003, entitled “Post-Partum Mammalian Placenta, Its Use and Placental Stem Cells Therefrom” which is hereby incorporated in its entirety.

In another embodiment of the invention, the stem or progenitor cells are not derived from a postpartum perfused placenta but instead, are isolated from other sources such as

cord blood, bone marrow, peripheral blood or adult blood, are exposed to the compounds of the invention and induced to differentiate. In a preferred embodiment, the differentiation is conducted *in vitro* under conditions appropriate, and for a time sufficient, to induce differentiation into the desired lineage or cell type. The compounds of the invention are used 5 in the differentiation/culture media by addition, in situ generation, or in any other manner that permits contact of the stem or progenitor cells with the compounds of the invention.

In another embodiment, the cultured stem cells, *e.g.*, stem cells cultured *in vitro* or in a postpartum perfused placenta, are stimulated to proliferate in culture, for example, by administration of erythropoietin, cytokines, lymphokines, interferons, colony stimulating 10 factors (CSFs), interferons, chemokines, interleukins, recombinant human hematopoietic growth factors including ligands, stem cell factors, thrombopoietin (Tpo), interleukins, and granulocyte colony-stimulating factor (G-CSF) or other growth factors.

After collection and/or isolation of the cultured cells, they may be identified and characterized by a colony forming unit assay, which is commonly known in the art, such as 15 Mesen Cult<sup>TM</sup> medium (stem cell Technologies, Inc., Vancouver British Columbia).

Methods for culturing stem or progenitor cells *in vitro* are well known in the art, *e.g.*, see, Thomson *et al.*, 1998, Science 282:1145-47 (embryonic stem cells); Hirashima *et al.*, 1999, Blood 93(4): 1253-63, and. Hatzopoulos *et al.*, 1998, Development 125:1457-1468 (endothelial cell progenitors); Slager *et al.*, 1993, Dev. Genet. 14(3):212-24 (neuron 20 or muscle progenitors); Genbachev *et al.*, 1995, Reprod. Toxicol. 9(3):245-55 (cytotrophoblasts, *i.e.*, placental epithelial cell progenitors); Nadkarni *et al.* 1984, Tumori 70:503-505, Melchner *et al.*, 1985, Blood 66(6): 1469-1472, international PCT publication WO 00/27999 published May 18, 2000, Himori *et al.*, 1984, Intl. J. Cell Cloning 2:254-262, and Douay *et al.*, 1995, Bone Marrow Transplantation 15:769-775 (hematopoietic progenitor 25 cells); Shambrott *et al.*, 1998, Proc. Natl. Acad. Sci. USA 95:13726-31 (primordial germ cells); Yan *et al.*, 2001, Devel. Biol. 235:422-432 (trophoblast stem cells). Such methods may be easily adapted for use in the methods of the invention, provided that the culture of the progenitor cells includes a step or steps of culturing the cells with a compound of the invention, at the times indicated, to produce the desired population(s) of differentiated cells.

#### 30           **5.4.1. Stem Cell Culture *in vitro***

The methods of the invention encompass the regulation of stem cell or progenitor cell differentiation *in vitro*, comprising incubating the cells with a compound, such as a small organic molecule of the present invention, *in vitro*, that induces them to differentiate into cells of a particular desired cell lineage, followed by direct transplantation of the

differentiated cells to a subject. In a preferred embodiment, the cells are induced to differentiate into a hematopoietic cell lineage.

In certain embodiments, the cultured stem cells of interest are exposed *in vitro* to a 0.1  $\mu\text{g}/\text{ml}$ , 0.2  $\mu\text{g}/\text{ml}$ , 0.3  $\mu\text{g}/\text{ml}$ , 0.4  $\mu\text{g}/\text{ml}$ , 0.5  $\mu\text{g}/\text{ml}$ , 1  $\mu\text{g}/\text{ml}$ , 5  $\mu\text{g}$  or 10  $\mu\text{g}/\text{ml}$  concentration of 5 a compound of the invention. Preferably the cells of interest are exposed to a concentration of Thalidomide of about 0.005  $\mu\text{g}/\text{ml}$  to about 5 mg/ml, a concentration of Actimid<sup>TM</sup> of about 0.005  $\mu\text{g}/\text{ml}$  to about 5 mg/ml, (Celgene Corp., Warren, NJ), a concentration of Revimid<sup>TM</sup> (Celgene Corp., Warren, NJ) of about 0.005  $\mu\text{g}/\text{ml}$  to about 5 mg/ml, a concentration of Actimid<sup>TM</sup> (Celgene Corp., Warren, NJ) of about 0.005  $\mu\text{g}/\text{ml}$  to about 5 mg/ml or a 10 concentration of Revimid<sup>TM</sup> (Celgene Corp., Warren, NJ) of about 0.005  $\mu\text{g}/\text{ml}$  to about 5 mg/ml (see also Section 5.7, "Pharmaceutical Compositions").

In certain embodiments, the embryonic-like stem cells are induced to propagate in the placenta bioreactor by introduction of nutrients, hormones, vitamins, growth factors, or any combination thereof, into the perfusion solution. Serum and other growth factors may be 15 added to the propagation perfusion solution or medium. Growth factors are usually proteins and include, but are not limited to: cytokines, lymphokines, interferons, colony stimulating factors (CSFs), interferons, chemokines, and interleukins. Other growth factors that may be used include recombinant human hematopoietic growth factors including ligands, stem cell factors, thrombopoietin (Tpo), granulocyte colony-stimulating factor (G-CSF), leukemia 20 inhibitory factor, basic fibroblast growth factor, placenta derived growth factor and epidermal growth factor.

The growth factors introduced into the perfusion solution can stimulate the propagation of undifferentiated embryonic-like stem cells, committed progenitor cells, or differentiated cells (*e.g.*, differentiated hematopoietic cells). The growth factors can 25 stimulate the production of biological materials and bioactive molecules including, but not limited to, immunoglobulins, hormones, enzymes or growth factors as previously described. The cultured placenta should be "fed" periodically to remove the spent media, depopulate released cells, and add fresh media. The cultured placenta should be stored under sterile conditions to reduce the possibility of contamination, and maintained under intermittent and 30 periodic pressurization to create conditions that maintain an ;adequate supply of nutrients to the cells of the placenta. It should be recognized that the perfusing and culturing of the placenta can be both automated and computerized for efficiency and increased capacity.

#### 5.4.2. Progenitor Cell Culture *in vitro*

The methods of the invention also encompass the regulation and modulation of the 35 development of progenitor cells, particularly CD34<sup>+</sup> and CD133<sup>+</sup> progenitor cells. In one

embodiment of the invention, progenitor cells are induced to differentiate into a hematopoietic cell lineage. In a specific embodiment, the lineage is a granulocytic lineage. In an alternate embodiment, CD133<sup>+</sup> cells are induced to differentiate into endothelial cells, brain cells, kidney cells, liver cells or intestinal tract cells.

5 Progenitor cells may be cultured by standard methods, as noted above. Additionally, the culture of the progenitor cells may comprise contacting the cells at various times or time frames during culture, so as to drive progenitor cell differentiation down different cell lineages.

10 Thus, in one method of culturing CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells, cells are plated at day 0 in medium containing stem cell factor (SCF), Flt-3L, GM-CSF and TNF- $\alpha$  and cultured for six days. On the sixth day, the cells are re-plated in medium containing GM-CSF and TNF- $\alpha$ , and culture is continued for an additional six days. This method results in the generation of dendritic cells. In a variation of this method, the cells are initially plated in medium containing GM-CSF and IL-4, then switched on the sixth day to monocyte-15 conditioned medium (see Steinman *et al.*, International Publication No. WO 97/29182). To produce a population of CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> progenitor cells, the progenitor cells are placed in contact with a compound of the invention at day 0, and CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> progenitor cells are collected at day 6.

20 The inventors have discovered that the timing of the addition of the compound(s) of the invention, particularly Actimid<sup>TM</sup> or Revimid<sup>TM</sup>, has a substantial effect upon the path of differentiation of CD34<sup>+</sup> cells into cells of particular lineages, and on the differentiation of CD133<sup>+</sup> cells. CD34<sup>+</sup> progenitor cells, cultured under standard conditions, follow a myeloid developmental pathway or lineage, *i.e.*, become dendritic cells within 12 days after initial plating (*i.e.*, after initial culture). However, the addition of a compound of the 25 invention at one of several particular times during the first six days of culture substantially alters this pathway. For example, if CD34<sup>+</sup> cells, particularly CD34<sup>+</sup> derived from bone marrow, are exposed to a compound of the invention, particularly Actimid<sup>TM</sup> or Revimid<sup>TM</sup> on the first day of culture, differentiation along the myeloid lineage is suppressed, as evidenced by the increase in the number of CD34<sup>+</sup>CD38<sup>-</sup> cells and decrease in the number 30 of CD1a<sup>+</sup>CD14<sup>-</sup> cells at day 6 of culture, relative to a control not exposed to a compound of the invention (*i.e.*, exposed to DMSO). Moreover, exposure to a compound of the invention leads to suppression of the development of cells expressing surface markers expressed by 35 cells in a dendritic cell lineage, such as CD80 and CD86. Contact at the initial day of culture, or at any point up to three days after the initial day of culture, with a compound of the invention, leads to such modulation of the development of CD34<sup>+</sup> progenitor cells. The

increase in the number of CD34<sup>+</sup> cells is intensified if multiple doses of a compound of the invention are given between day 0 and day 6, for example, doses at day 0 and day 2, day 0 and day 4, doses at day 3 and day 6, or doses at day 2, day 4, and day 6.

In a particularly useful aspect of the invention, the addition of a compound of the invention at the first day of CD34<sup>+</sup> progenitor cell culture, and continuing the exposure through day 12, leads to the development of a unique progenitor cell expressing a unique combination of cell surface markers: CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup>. The CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> cell population represents an intermediate stage in differentiation. This population is useful as an expandable population of progenitor cells that may readily be transplanted to a patient in need of a rapidly-developing population of hematopoietic lineage cells, for example, granulocytic cells. In another embodiment, CD34<sup>+</sup> cells may be plated and cultured during the proliferative phase (approximately 6 days) in standard medium (*i.e.*, not exposed to Actimid™, Revimid™ or the like), then switched to the same or a similar medium containing Actimid™ or the like, and continuing the culture until day 12. In this embodiment, the differentiating cells typically show decreased expression of CD80, CD86 and CD14, but result in an increased persistence of a CD1a<sup>+</sup> cell population relative to controls. Such differentiating cells are not blocked from becoming dendritic cells. In another embodiment, CD34<sup>+</sup> cells are treated during the proliferative phase (days 1-6 post-plating) for at least three consecutive days with Actimid™, Revimid™, or another compound of the invention. In yet another embodiment, CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells are treated two or more times with Actimid™, Revimid™, or another compound of the invention, during the first six days after plating. Such multiple treatments result in an increase in the proliferation of both CD34<sup>+</sup> or CD133<sup>+</sup> populations. Multiple treatments with Actimid™, or another compound of the invention, also causes a shift in the differentiation of CD34<sup>+</sup> progenitor cells away from a CD11c<sup>+</sup>CD15<sup>-</sup> lineage and towards a CD11c<sup>-</sup>CD15<sup>+</sup> lineage, *i.e.*, away from a myeloid dendritic cell lineage and towards a granulocytic lineage (FIG. 6B).

Treatment of the progenitor cells from day 0 of culture, particularly multiple doses between day 0 and day 6, also results in an increase in the number of CD133<sup>+</sup> progenitor cells, particularly an increase in the CD34<sup>+</sup>CD133<sup>+</sup> progenitor population. CD133 is a hematopoietic marker that is an alternative to CD34 isolation, as CD133<sup>+</sup> cells can be expanded in the same manner as the CD34<sup>+</sup> subset and conserve their multilineage capacity (*see* Kobari *et al.*, *J. Hematother. Stem Cell Res.* 10(2):273-81 (2001)). CD133<sup>+</sup> has been reported to be present in CD34<sup>-</sup> cells from human fetal brain tissue, and showed potent engraftment, proliferation, migration, and neural differentiation when injected into neonatal

mice (*see Proc. Natl. Acad. Sci. U.S.A.* 19:97(26):14720-5 (2000)). CD133<sup>+</sup> hematopoietic stem cells have been shown to be enriched for progenitor activity with enlarged clonogenic capacity and higher engraftment in NOD-SCID mice.

The above notwithstanding, if a compound of the invention is placed in contact with 5 proliferating CD34<sup>+</sup> progenitor cells after three days of culture (*i.e.*, at any time between 3-6 days after initial culture), the proliferating progenitor cells, which have already begun expressing the cell surface marker CD1a, show a substantially increased persistence of the expression of this marker relative to DMSO-treated controls. It is important to note that no cytotoxicity is associated with this increased persistence. In other words, treatment with 10 Actimid<sup>TM</sup> does not cause other cell populations to apoptose. The net effect is a maintenance of existing immune capability and the development of new immune capability.

Thus, in one embodiment of the method of the invention, differentiation of CD34<sup>+</sup> cells into dendritic cells is modulated (*i.e.*, suppressed) by contacting CD34<sup>+</sup> progenitor cells with a compound of the invention at day 0 of culture (*i.e.*, the first day of culture). In 15 another embodiment, differentiation of CD34<sup>+</sup> cells into granulocytic cells is enhanced by contacting CD34<sup>+</sup> progenitor cells with a compound of the invention at day 0 of culture (*i.e.*, the first day of culture). In another embodiment, differentiation of CD34<sup>+</sup> cells into a CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or a CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> progenitor cell population is enhanced by contacting CD34<sup>+</sup> progenitor cells with a compound of the invention during the first three 20 days of culture. In another embodiment, a CD34<sup>+</sup>CD133<sup>+</sup> population is enhanced or increased by contacting progenitor cells with a compound of the invention in multiple doses from day 0 to day 6 of culture. In another embodiment, the persistence of a CD1a<sup>+</sup> cell population is enhanced or increased by contacting CD34<sup>+</sup> progenitor cells with a compound of the invention at day 6 of culture, wherein said CD34<sup>+</sup> cells differentiate into cells 25 exhibiting the CD1a surface marker, and wherein said culture includes no contact with said compound for up to six days.

In the above embodiments, it will be understood that such variations in administration of Actimid<sup>TM</sup>, Revimid<sup>TM</sup>, or a related compound may be made to the progenitor cells *in vivo*, *e.g.*, such as in a patient into whom such cells have been 30 transplanted or engrafted, as well as to the progenitor cells *in vitro*.

The methods of the invention encompass the regulation of stem cell or progenitor cell differentiation *in vitro*, comprising incubating the cells with a compound, such as a small organic molecule of the present invention, *in vitro*, that induces them to differentiate into cells of a particular desired cell lineage, followed by direct transplantation of the 35 differentiated cells to a subject. In a preferred embodiment, the cells are induced to

differentiate into a hematopoietic cell lineage. In an alternate embodiment, CD133<sup>+</sup> cells are induced to differentiate into endothelial cells, brain cells, kidney cells, liver cells, or intestinal tract cells.

It should be noted that the methods described herein are contemplated for use with  
5 CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells derived from mammals, preferably humans, but are also contemplated for use with avian or reptilian progenitor cells. The compounds of the invention, however, are potentially variably potent depending upon the species from which the progenitor cells are derived. Some variation in the culturing methods, particularly with regard to the concentration of the compound(s) administered, is therefore also contemplated.  
10 For example, progenitor cells of murine origin are less sensitive to the compounds of the invention, for example Actimid™, and would require higher concentrations to achieve the effects obtainable at 1 µM with progenitor cells of human origin. Persons of skill in the art would understand that such optimizations are routine.

### 5.5. GENETIC ENGINEERING OF STEM AND PROGENITOR CELLS

15 In another embodiment of the invention, stem or progenitor cells to be differentiated in accordance with the methods of the invention are genetically engineered either prior to, or after exposure to the compounds of the invention, using, for example, a viral vector such as an adenoviral or retroviral vector, or by using mechanical means such as liposomal or chemical mediated uptake of the DNA. In specific embodiments, the CD34<sup>+</sup> progenitor cells  
20 are genetically engineered, then treated with a compound of the invention; in more specific embodiments, said compound is Actimid™, Revimid™, or an analog of either. In another embodiment, said cells are treated with a compound of the invention, then genetically engineered.

A vector containing a transgene can be introduced into a cell of interest by methods well  
25 known in the art, e.g., transfection, transformation, transduction, electroporation, infection, microinjection, cell fusion, DEAE dextran, calcium phosphate precipitation, liposomes, LIPOFECTIN™, lysosome fusion, synthetic cationic lipids, use of a gene gun or a DNA vector transporter, such that the transgene is transmitted to daughter cells, e.g., the daughter embryonic-like stem cells or progenitor cells produced by the division of an embryonic-like  
30 stem cell. For various techniques for transformation or transfection of mammalian cells, see Keown *et al.*, 1990, Methods Enzymol. 185: 527-37; Sambrook *et al.*, 2001, Molecular Cloning, A Laboratory Manual, Third Edition, Cold Spring Harbor Laboratory Press, N.Y.

Preferably, the transgene is introduced using any technique, so long as it is not destructive to the cell's nuclear membrane or other existing cellular or genetic structures. In  
35 certain embodiments, the transgene is inserted into the nucleic genetic material by

microinjection. Microinjection of cells and cellular structures is commonly known and practiced in the art.

For stable transfection of cultured mammalian cells, such as cells culture in a placenta, only a small fraction of cells may integrate the foreign DNA into their genome. The 5 efficiency of integration depends upon the vector and transfection technique used. In order to identify and select integrants, a gene that encodes a selectable marker (*e.g.*, for resistance to antibiotics) is generally introduced into the host embryonic-like stem cell along with the gene sequence of interest. Preferred selectable markers include those that confer resistance to drugs, such as G418, hygromycin and methotrexate. Cells stably transfected with the 10 introduced nucleic acid can be identified by drug selection (*e.g.*, cells that have incorporated the selectable marker gene will survive, while the other cells die). Such methods are particularly useful in methods involving homologous recombination in mammalian cells (*e.g.*, in embryonic-like stem cells) prior to introduction or transplantation of the recombinant cells into a subject or patient.

15 A number of selection systems may be used to select transformed host stem cells, such as embryonic-like cells, or progenitor cells, such as CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells. In particular, the vector may contain certain detectable or selectable markers. Other methods of selection include but are not limited to selecting for another marker such as: the herpes simplex virus thymidine kinase (Wigler *et al.*, 1977, Cell 11: 223), hypoxanthine- 20 guanine phosphoribosyltransferase (Szybalska and Szybalski, 1962, Proc. Natl. Acad. Sci. USA 48: 2026), and adenine phosphoribosyltransferase (Lowy *et al.*, 1980, Cell 22: 817) genes can be employed in tk-, hgprt- or aprt- cells, respectively. Also, antimetabolite resistance can be used as the basis of selection for the following genes: dhfr, which confers 25 resistance to methotrexate (Wigler *et al.*, 1980, Proc. Natl. Acad. Sci. USA 77: 3567; O'Hare *et al.*, 1981, Proc. Natl. Acad. Sci. USA 78: 1527); gpt, which confers resistance to mycophenolic acid (Mulligan and Berg, 1981, Proc. Natl. Acad. Sci. USA 78: 2072); neo, which confers resistance to the aminoglycoside G-418 (Colberre-Garapin *et al.*, 1981, J. Mol. Biol. 150: 1); and hygro, which confers resistance to hygromycin (Santerre *et al.*, 1984, Gene 30: 147).

30 The transgene may integrate into the genome of the cell of interest, preferably by random integration. In other embodiments the transgene may integrate by a directed method, *e.g.*, by directed homologous recombination (*i.e.*, “knock-in” or “knock-out” of a gene of interest in the genome of cell of interest), Chappel, U.S. Patent No. 5,272,071; and PCT publication No. WO 91/06667, published May 16, 1991; U.S. Patent 5,464,764; Capecchi *et al.*,

issued November 7, 1995; U.S. Patent 5,627,059, Capecchi *et al.* issued, May 6, 1997; U.S. Patent 5,487,992, Capecchi *et al.*, issued January 30, 1996).

Methods for generating cells having targeted gene modifications through homologous recombination are known in the art. The construct will comprise at least a portion of a gene of interest with a desired genetic modification, and will include regions of homology to the target locus, *i.e.*, the endogenous copy of the targeted gene in the host's genome. DNA constructs for random integration, in contrast to those used for homologous recombination, need not include regions of homology to mediate recombination. Markers can be included in the targeting construct or random construct for performing positive and negative selection for insertion of the transgene.

To create a homologous recombinant cell, *e.g.*, a homologous recombinant embryonic like stem cell, endogenous placental cell or exogenous cell cultured in the placenta, a homologous recombination vector is prepared in which a gene of interest is flanked at its 5' and 3' ends by gene sequences that are endogenous to the genome of the targeted cell, to allow for homologous recombination to occur between the gene of interest carried by the vector and the endogenous gene in the genome of the targeted cell. The additional flanking nucleic acid sequences are of sufficient length for successful homologous recombination with the endogenous gene in the genome of the targeted cell. Typically, several kilobases of flanking DNA (both at the 5' and 3' ends) are included in the vector.

Methods for constructing homologous recombination vectors and homologous recombinant animals from recombinant stem cells are commonly known in the art (*see, e.g.*, Thomas and Capecchi, 1987, Cell 51: 503; Bradley, 1991, Curr. Opin. Bio/Technol. 2: 823-29; and PCT Publication Nos. WO 90/11354, WO 91/01140, and WO 93/04169.

In a specific embodiment, the methods of Bonadio *et al.* (U.S. Patent No. 5,942,496, entitled Methods and compositions for multiple gene transfer into bone cells, issued August 24, 1999; and PCT W095/22611, entitled Methods and compositions for stimulating bone cells, published August 24, 1995 ) are used to introduce nucleic acids into a cell of interest, such as a stem cell, progenitor cell or exogenous cell cultured in the placenta, *e.g.*, bone progenitor cells.

## 5.6. USES OF STEM CELLS AND PROGENITOR CELLS CONDITIONED FOR DIFFERENTIATION

### 5.6.1. General Uses

The stem cells and CD34<sup>+</sup> and CD133<sup>+</sup> progenitor of the invention may be induced to differentiate for use in transplantation and ex vivo treatment protocols. In one embodiment, the stem cell populations are differentiated to a particular cell type and genetically engineered to provide a therapeutic gene product. In another embodiment, the progenitor cell

populations are expanded into early progenitor cells and genetically engineered to provide a therapeutic gene product. In another embodiment, the progenitor cell populations are differentiated to a particular cell type, such as a granulocyte, and genetically engineered to provide a therapeutic gene product.

5       The compounds of the invention also have utility in clinical settings in which transplantation has the principle objective of restoring bone marrow white blood cell production, such as the reversal of neutropenia and leukopenia, which result from disease and/or clinical myeloablation. The compounds also have utility in the restoration of production of early progenitor cells or granulocytes, which result from disease, various  
10      known therapeutic side effects, or myeloablation. The compounds of the invention also have utility in cases in which the suppression of red blood cell generation is preferred, without bone marrow suppression.

15      In certain embodiments, stem cells that have been treated with the compounds of the invention are administered along with untreated cells, such as stem cells from cord blood or peripheral blood, to a patient in need thereof. In other embodiments, CD34<sup>+</sup> or CD133<sup>+</sup> cells that have been treated with the compounds of the invention are administered along with untreated cells, such as stem cells from cord blood or peripheral blood, to a patient in need thereof. In one embodiment, CD34<sup>+</sup> progenitor cells, treated from the first day of culture with a compound of the invention, are administered with untreated cells to a patient  
20      in need thereof. In a more specific embodiment, the progenitor cell transferred is a CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or a CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> progenitor cell.

25      Stem cells, *e.g.*, embryonic-like or hematopoietic stem cells, or progenitor cells, the differentiation of which has been modulated according to the methods of the invention, may be formulated as an injectable (*see* PCT WO 96/39101, incorporated herein by reference in its entirety). In an alternative embodiment, cells and tissues, the differentiation of which has been modulated according to the methods of the invention, may be formulated using polymerizable or cross linking hydrogels as described in U.S. Patent Nos. 5,709,854; 5,516,532; or 5,654,381, each of which is incorporated by reference in its entirety.

30      Embryonic-like stem cells may be used instead of specific classes of progenitor cells (*e.g.*, chondrocytes, hepatocytes, hematopoietic cells, pancreatic parenchymal cells, neuroblasts, muscle progenitor cells, etc.) in therapeutic or research protocols in which progenitor cells would typically be used.

#### **5.6.2. Tissue Replacement or Augmentation**

35      The stem cells, particularly embryonic-like stem cells, and progenitor cells, of the invention, the differentiation of which has been modulated according to the methods of the

invention, can be used for a wide variety of therapeutic protocols directed to the transplantation or infusion of a desired cell population, such as a stem cell or progenitor cell population. The stem or progenitor cells can be used to replace or augment existing tissues, to introduce new or altered tissues, or to join together biological tissues or structures.

5        In a preferred embodiment of the invention, stem cells, such as embryonic-like stem cells from the placenta, or progenitor cells such as hematopoietic progenitor cells, the differentiation of which has been modulated according to the methods of the invention, may be used as autologous and allogenic, including matched and mismatched HLA type, hematopoietic transplants. In accordance with the use of embryonic-like stem cells as  
10      allogenic hematopoietic transplants, it may be preferable to treat the host to reduce immunological rejection of the donor cells, such as those described in U.S. Patent No. 5,800,539, issued September 1, 1998; and U.S. Patent No. 5,806,529, issued September 15, 1998, both of which are incorporated herein by reference.

15      For example, embryonic-like stem cells, the differentiation of which has been modulated according to the methods of the invention can be used in therapeutic transplantation protocols, *e.g.*, to augment or replace stem or progenitor cells of the liver, pancreas, kidney, lung, nervous system, muscular system, bone, bone marrow, thymus, spleen, mucosal tissue, gonads, or hair. Likewise, hematopoietic progenitor cells, the differentiation of which has been modulated according to the methods of the invention, may  
20      be used instead of bone marrow or endothelial progenitor cells.

25      Stem cells, for example embryonic-like stem cells, the differentiation of which has been modulated according to the methods of the invention, can be used for augmentation, repair or replacement of cartilage, tendon, or ligaments. For example, in certain embodiments, prostheses (*e.g.*, hip prostheses) are coated with replacement cartilage tissue constructs grown from embryonic-like stem cells of the invention. In other embodiments, joints (*e.g.*, knee) are reconstructed with cartilage tissue constructs grown from embryonic-like stem cells. Cartilage tissue constructs can also be employed in major reconstructive surgery for different types of joints (for protocols, see *e.g.*, Resnick, D., and Niwayama, G., *eels.*, 1988, Diagnosis of Bone and Joint Disorders, 2d ed., W. B. Saunders Co.).

30      The stem cells and progenitor cells treated according to the methods of the invention can be used to repair damage of tissues and organs resulting from disease. In such an embodiment, a patient can be administered embryonic-like stem cells to regenerate or restore tissues or organs which have been damaged as a consequence of disease, *e.g.*, enhance immune system following chemotherapy or radiation, repair heart tissue following  
35      myocardial infarction. Stem and/or progenitor cells treated according to the methods, and

with the immunomodulatory compounds, of the invention, or administered in conjunction with the immunomodulatory compounds of the invention, may be transplanted into an individual in need thereof to repair and/or replace hepatic, pancreatic or cardiac tissue.

The stem cells and progenitor cells treated according to the methods of the invention can  
5 also be used to augment or replace bone marrow cells in bone marrow transplantation.  
Human autologous and allogenic bone marrow transplantation is currently used as a therapy  
for diseases such as leukemia, lymphoma and other life-threatening disorders. The  
drawback of these procedures, however, is that a large amount of donor bone marrow must  
be removed to insure that there is enough cells for engraftment.

10 The embryonic-like stem cells collected according to the methods of the invention  
can provide stem cells and progenitor cells that would reduce the need for large bone  
marrow donation. It would also be, according to the methods of the invention, to obtain a  
small marrow donation and then expand the number of stem cells and progenitor cells  
culturing and expanding in the placenta before infusion or transplantation into a recipient.

15 The large numbers of embryonic-like stem cells and/or progenitor obtained using the  
methods of the invention would, in certain embodiments, reduce the need for large bone  
marrow donations. Approximately  $1 \times 10^8$  to  $2 \times 10^8$  bone marrow mononuclear cells per  
kilogram of patient weight must be infused for engraftment in a bone marrow transplantation  
(*i.e.*, about 70 ml of marrow for a 70 kg donor). To obtain 70 ml requires an intensive  
20 donation and significant loss of blood in the donation process. In a specific embodiment,  
cells from a small bone marrow donation (*e.g.*, 7-10 ml) could be expanded by propagation,  
for example in a placental bioreactor, before infusion into a recipient. The stem cells, and  
progenitor cells, particularly CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells, the differentiation of which  
has been modulated according to the methods of the invention, can thus provide stem and/or  
25 progenitor cells that would reduce or eliminate the need for a large bond marrow donation.

The embryonic-like stem cells isolated from the placenta may be used, in specific  
embodiments, in autologous or heterologous enzyme replacement therapy to treat specific  
diseases or conditions, including, but not limited. to lysosomal storage diseases, such as Tay-  
Sachs, Niemann-Pick, Fabry's, Gaucher's, Hunter's, Hurler's syndromes, as well as other  
30 gangliosidoses, mucopolysaccharidoses, and glycogenoses.

In other embodiments, the cells may be used as autologous or heterologous  
transgene carriers in gene therapy to correct inborn errors of metabolism such as  
adrenoleukodystrophy, cystic fibrosis, glycogen storage disease, hypothyroidism, sickle cell  
anemia, Pearson syndrome, Pompe's disease, phenylketonuria (PKU), and Tay-Sachs  
35 disease, porphyrias, maple syrup urine disease, homocystinuria, mucopolysaccharidenosis,

chronic granulomatous disease, and tyrosinemia, or to treat cancer, tumors or other pathological conditions.

In other embodiments, the cells may be used in autologous or heterologous tissue regeneration or replacement therapies or protocols, including, but not limited to treatment of  
5 corneal epithelial defects, cartilage repair, facial dermabrasion, mucosal membranes, tympanic membranes, intestinal linings, neurological structures (*e.g.*, retina, auditory neurons in basilar membrane, olfactory neurons in olfactory epithelium), burn and wound repair for traumatic injuries of the skin, scalp (hair) transplantation, or for reconstruction of other damaged or diseased organs or tissues.

10 Furthermore, a small number of stem cells and progenitor cells normally circulate in the blood stream. In another embodiment, such exogenous stem cells or exogenous progenitor cells are collected by apheresis, a procedure in which blood is withdrawn, one or more components are selectively removed, and the remainder of the blood is reinfused into the donor. The exogenous cells recovered by apheresis are expanded by the methods of the  
15 invention, thus eliminating the need for bone marrow donation entirely.

In another embodiment, expansion of hematopoietic progenitor cells in accordance with the methods of the invention is used as a supplemental treatment in addition to chemotherapy. Most chemotherapy agents used to target and destroy cancer cells act by killing all proliferating cells, *i.e.*, cells going through cell division. Since bone marrow is one of the  
20 most actively proliferating tissues in the body, hematopoietic stem cells are frequently damaged or destroyed by chemotherapy agents and in consequence, blood cell production is diminishes or ceases. Chemotherapy must be terminated at intervals to allow the patient's hematopoietic system to replenish the blood cell supply before resuming chemotherapy. It may take a month or more for the formerly quiescent stem cells to proliferate and increase the white  
25 blood cell count to acceptable levels so that chemotherapy may resume (when again, the bone marrow stem cells are destroyed).

While the blood cells regenerate between chemotherapy treatments, however, the cancer has time to grow and possibly become more resistant to the chemotherapy drugs due to natural selection. Therefore, the longer chemotherapy is given and the shorter the  
30 duration between treatments, the greater the odds of successfully killing the cancer. To shorten the time between chemotherapy treatments, embryonic-like stem cells or progenitor cells differentiated in accordance with the methods of the invention could be introduced into the patient. Such treatment would reduce the time the patient would exhibit a low blood cell count, and would therefore permit earlier resumption of the chemotherapy treatment.

In another embodiment, the human placental stem cells can be used to treat or prevent genetic diseases such as chronic granulomatous disease.

### 5.6.3. Amelioration of Inflammation

The stem and progenitor cells, the differentiation of which has been modulated according to the methods of the invention, may be used as general anti-inflammatory agents. The inventors have discovered that stem and progenitor cells from, for example, cord blood, when transplanted into a patient, reduce or substantially eliminate the inflammatory response. Thus, in one embodiment, the methods of the invention comprise administering to a patient having an inflammatory response, or who is likely to develop an inflammatory response, stem cells or progenitor cells whose differentiation has been modulated by one or more of the compounds of the invention. In specific embodiments, the stem cells are embryonic-like stem cells, and the progenitor cells are hematopoietic stem cells, particularly CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells.

The inventors have also discovered that treatment of an individual with the compounds of the inventions, *i.e.*, IMiDs, stimulates the development and differentiation of cells that modulate, ameliorate or reduce the inflammatory response. Thus, another embodiment of the invention comprises a method of treating an individual having an inflammatory response, or who is likely to develop an inflammatory response, comprising administering an effective dose of one or more of the compounds of the invention to said individual. In another embodiment, the method comprises contacting stem or progenitor cells with the compounds of the invention prior to administration to said individual, then administering a therapeutically effective dose of said cells to said individual. In yet another embodiment, cell so treated may be co-administered with one or more of the compounds of the invention to said individual in therapeutically-effective doses.

In other embodiments, inflammation may be reduced by administration of other compounds in combination with the compounds and/or cells of the invention. For example, such additional compounds may comprise steroids, such as prednisone, or any of the non-steroidal anti-inflammatory agents, such as the cox-1/cox-2 inhibitors acetylsalicylic acid (aspirin), ibuprofen, acetaminophen, cox-1-specific inhibitors, or derivatives of any of these compounds. Such additional anti-inflammatory agents may be delivered by any standard route, such as intravenously, topically, intradermally, or by inhalation, and may be delivered contemporaneously with the compounds and/or cell of the invention, or at different times.

The above methods may be used to treat any disease or condition associated with, caused by, or resulting in inflammation. For example, the methods may be used to treat inflammation caused by trauma such as accidental injury. The methods may also be used to

treat inflammation caused by or injury that is associated with surgical procedures, in particular vessel-related surgical procedures such as grafts of natural tissue, synthetic vascular grafts, heart valves or angioplasties. The methods may also be used to prevent stenosis or restenosis. The methods above may also be used to treat inflammation resulting  
5 from any disease or condition, including but not limited to diseases or conditions such as heart disease, atherosclerosis, allergy or hypersensitivity, immune disorder, autoimmune disorder such as arthritis, or inflammations due to infections. In addition to treating a inflammatory condition that already exists, the cells and/or compounds of the invention may be administered to an individual prophylactically, so as to reduce the occurrence of  
10 inflammation. This is particularly useful as a form of pre-operative therapy, whereby reduction of the post-operative inflammatory response improves an individual's chances for a successful outcome and reduces hospital stay time and periods of disability.

Monitoring of the effectiveness of the anti-inflammatory effect of the above treatments may be accomplished by any known methods, such as visual inspection, MRI or  
15 CAT scans, determination of systemic or local temperature, etc. Because a protein known as C-reactive protein is a marker for inflammation, the effectiveness of the above treatment methods may be monitored by assaying for a reduction in the amount of C-reactive protein in an individual, particularly in the area formerly experiencing inflammation.

#### 5.6.4. Production of Dendritic Cell and Granulocyte Cell Populations

20 The compounds of the invention may be administered specifically to modulate the differentiation of stem and/or progenitor cells along a granulocytic developmental pathway versus a dendritic cell developmental pathway. In a like manner, the cell of the invention may be modulated *in vivo* or *ex vivo* to produce expanded populations of dendritic cells or granulocytes.

25 Dendritic cells can be used as reagents for immune-based therapies. For example, dendritic cells can be co-cultured with T lymphocytes and protein antigen *in vitro*, thus driving the *ex vivo* antigen-specific activation of T cells. The activated T cells are then administered autologously to effect an antigen-specific immune response *in vivo* (WO 97/24438). In another example, T cells can be activated *in vitro* by contacting the T  
30 lymphocytes with dendritic cells that directly express an antigenic protein from a recombinant construct. The activated T cells can be used for autologous infusion (WO 97/29183).

T cells activated with specific peptides or protein fragments become immunizing agents against the proteins, cells or organisms from which the peptides or fragments were  
35 derived. For example, dendritic cells may be loaded with tumor-specific peptides. Specific

application of DC-driven *ex vivo* T cell activation to the treatment of prostate cancer is described and claimed in U.S. Pat. No. 5,788,963. Mayordomo *et al.* demonstrated bone marrow-derived dendritic cells pulsed with synthetic tumor peptides elicit protective and therapeutic anti-tumor immunity (*Nature Medicine* 1:1297-1302 (1995); *J. Exp. Med.*, 5 183:1357-1365 (1996)). The U.S. Pat. No. 5,698,679 describes immunoglobulin fusion proteins that deliver antigenic peptides to targeted antigen presenting cells (APCs), including dendritic cells, *in vivo*. This same approach may be used with peptides or antigens derived from viruses, bacteria, or parasites to create viral, bacterial, or parasitic vaccines.

10 Dendritic cells are also targets for therapeutic intervention in the treatment of various immune-mediated disorders. For example, dendritic cells have been implicated as an important player in the pathogenesis and pathophysiology of AIDS (e.g., serve as reservoirs for the HIV virus). See Zoetewij *et al.*, *J. Biomed. Sci.* 5(4):253-259 (1998); Grouard *et al.*, *Curr. Opin. Immunol.* 9(4):563-567 (1997); Weissman *et al.*, *Clin. 15 Microbiol. Rev.* 10(2):358-367 (1997). *In vitro* methods for screening pharmaceutical candidates for agents that abrogate HIV infection of DC are described in U.S. Pat. No. 5,627,025. In another example, dendritic cells can be manipulated to induce T cell unresponsiveness to donor tissue or organ in a recipient (see U. S. Pat. No. 6,375,950).

20 Granulocytes can be used in granulocyte transfusions in the treatment or prevention of infections, e.g., bacterial neonatal sepsis, neutropenia-associated infections in cancer patients, and potential infections in patients receiving bone-marrow transplants.

Granulocytes can also be used in prevention or treatment of allergy. For example, 25 granulocytes involved in IgE-mediated inflammation (*i.e.*, granulocytes coated with IgE antibodies some of which having specificity for the allergen) can be inactivated and used to alleviate the symptoms of an already established immune response against the allergen (see U.S. Pat. No. 6,383,489).

Thus, in one embodiment of the invention, a population of granulocytes in an individual is expanded from the progenitor cells of the invention by a method comprising 30 administering to said individual a therapeutically-effective amount of a compound of the invention, wherein said amount is sufficient to induce the production of a plurality of granulocytes from CD34<sup>+</sup> cells endogenous to said individual. In another embodiment, a population of granulocytes is expanded within an individual by a method comprising administering to said individual a population of CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells, wherein 35 said cells have been contacted with a compound of the invention for at least three days, and administering said population of cells to said individual. In another embodiment,

population of granulocytes is expanded within an individual by a method comprising administering to said individual a population of CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells and a compound of the invention, wherein the dose of said compound of the invention is sufficient to cause differentiation of a plurality of said population of cell into granulocytes. In a 5 specific embodiment of the above embodiments, said CD34<sup>+</sup> progenitor cells are CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> cells.

#### **5.6.5. Treatment of Other Diseases and Conditions**

The differentiated stem and progenitor cells of the invention, or the compounds of the invention, may also be used, alone or in combination, to treat or prevent a variety of other diseases or conditions. In certain embodiments, for example, the disease or disorder includes, but is not limited to, but not limited to a vascular or cardiovascular disease, atherosclerosis, diabetes, aplastic anemia, myelodysplasia, myocardial infarction, seizure disorder, multiple sclerosis, stroke, hypotension, cardiac arrest, ischemia, inflammation, age-related loss of cognitive function, radiation damage, cerebral palsy, neurodegenerative 10 disease, Alzheimer's disease, Parkinson's disease, Leigh disease, AIDS dementia, memory loss, amyotrophic lateral sclerosis (ALS), ischemic renal disease, brain or spinal cord trauma, heart-lung bypass, glaucoma, retinal ischemia, retinal trauma, lysosomal storage diseases, such as Tay-Sachs, Niemann-Pick, Fabry's, Gaucher's, Hunter's, and Hurler's 15 syndromes, as well as other gangliosidoses, mucopolysaccharidoses, glycogenoses, inborn errors of metabolism, adrenoleukodystrophy, cystic fibrosis, glycogen storage disease, 20 hypothyroidism, sickle cell anemia, Pearson syndrome, Pompe's disease, phenylketonuria (PKU), porphyrias, maple syrup urine disease, homocystinuria, mucopolysaccharidosis, chronic granulomatous disease and tyrosinemia, Tay-Sachs disease, cancer, tumors or other pathological or neoplastic conditions.

In other embodiments, the cells of the invention (e.g., which have been exposed to the compounds of the invention) may be used in the treatment of any kind of injury due to trauma, particularly trauma involving inflammation. Examples of such trauma-related 25 conditions include central nervous system (CNS) injuries, including injuries to the brain, spinal cord, or tissue surrounding the CNS injuries to the peripheral nervous system (PNS); or injuries to any other part of the body. Such trauma may be caused by accident, or may be 30 a normal or abnormal outcome of a medical procedure such as surgery or angioplasty. The trauma may be related to a rupture or occlusion of a blood vessel, for example, in stroke or phlebitis. In specific embodiments, the cells may be used in autologous or heterologous tissue regeneration or replacement therapies or protocols, including, but not limited to 35 treatment of corneal epithelial defects, cartilage repair, facial dermabrasion, mucosal

membranes, tympanic membranes, intestinal linings, neurological structures (*e.g.*, retina, auditory neurons in basilar membrane, olfactory neurons in olfactory epithelium), burn and wound repair for traumatic injuries of the skin, or for reconstruction of other damaged or diseased organs or tissues.

5 In a specific embodiment, the disease or disorder is aplastic anemia, myelodysplasia, leukemia, a bone marrow disorder or a hematopoietic disease or disorder. In another specific embodiment, the subject is a human.

### 5.7. PHARMACEUTICAL COMPOSITIONS

The present invention encompasses pharmaceutical compositions comprising a dose 10 and/or doses of one or more of the compounds of the invention, wherein said dose or doses are effective upon single or multiple administration, prior to or following transplantation of conditioned or unconditioned human CD34<sup>+</sup> or CD133<sup>+</sup> progenitor or stem cells to an individual, exerting effect sufficient to inhibit, modulate and/or regulate the differentiation of these stem and/or progenitor cells into specific cell types, *e.g.*, hematopoietic lineage cells, 15 particularly myeloid lineage cells. In this context, as elsewhere in the context of this invention, “individual” means any individual to which the compounds or cells are administered, *e.g.*, a mammal, bird or reptile.

Thus, in a specific embodiment, said dose or doses of the compounds of the invention, administered to an individual, modulate the differentiation of endogenous CD34<sup>+</sup> 20 progenitor cells into dendritic cells. In a more specific embodiment, the dose or doses increase the number of granulocytic cells in said individual to which said dose or doses have been administered. In another more specific embodiment, the dose or doses increase the number of CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> progenitor cells in a mammal to which said dose or doses have been administered.

25 In other embodiments, CD34<sup>+</sup> or CD133<sup>+</sup> progenitor or stem cells of interest are transplanted into human subject or patient in need thereof. Subsequent to transplantation, a compound of the invention is administered to the human subject or patient, to modulate the differentiation of the transplanted cells of interest *in vivo*. In a specific embodiment, such cells are differentiated *in vivo* into granulocytes. In yet other embodiments, the 30 differentiation of progenitor or stem cells of interest in a human subject or patient is modulated *in situ* by administration of a compound of the invention.

In yet another embodiment, the invention provides pharmaceutical compositions comprising isolated cord blood stem or progenitor cell populations that have been augmented with hematopoietic progenitor cells that have been differentiated by exposure to compounds 35 that inhibit TNF- $\alpha$  activity, in accordance with the methods of the invention. In another

embodiment, the invention provides pharmaceutical compositions comprising cord blood that is supplemented with stem or progenitor cells contacted with the compounds of the invention; in a specific embodiment, said stem or progenitor cells have been differentiated by said compounds.

5        In yet another embodiment, the invention provides for pharmaceutical compositions comprising both one or more of the immunomodulatory compounds of the invention, and the stem and/or progenitor cells of the invention. Such compositions may be prepared 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 or 12 days in advance of administration so as to modulate the differentiation of the stem and/or progenitor cells along different  
10 developmental/differentiation pathways.

In yet another embodiment, the pharmaceutical compositions of the present invention may comprise the stem or progenitor cells themselves, wherein said cells have been differentiated according to the methods disclosed herein. Thus, the present invention provides a pharmaceutical composition comprising a plurality of stem cells and/or progenitor cells,  
15 wherein said plurality of stem and/or progenitor cells has been contacted with one or more of the immunomodulatory compounds of the invention in a concentration and for a duration sufficient for said compound(s) to modulate differentiation of said cells.

Thus, the pharmaceutical compositions of the invention comprise the compounds of the invention, administered to an individual; the cells of the invention, administered to an  
20 individual, in combination with the compounds of the invention, separately administered; and the cells of the invention, contacted with the compounds of the invention, administered to said individual.

The invention provides methods of treatment and prevention of a disease or disorder by administration of a therapeutically effective amount of a compound or a composition of the  
25 invention to a mammalian, preferably human, subject, in order to effect modulation of the proliferation and/or differentiation of CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells or stem cells transplanted to, or residing within the subject. In one embodiment, the invention provides a method of modulating the differentiation of CD34<sup>+</sup> and CD133<sup>+</sup> progenitor or stem cells so as to increase within a mammal the number of granulocytic cells. In another embodiment,  
30 any cell lineage that may be derived from a CD34<sup>+</sup> and/or CD133<sup>+</sup> progenitor or stem cell may be modulated by administration of the compounds of the invention to a mammal, preferably to a human. The term "mammal" as used herein, encompasses any mammal. Preferably a mammal is in need of such treatment or prevention. Examples of mammals include, but are not limited to, cows, horses, sheep, pigs, cats, dogs, mice, rats, rabbits, guinea  
35 pigs, monkeys, etc., more preferably, a human.

Administration of compounds of the invention can be systemic or local. In most instances, administration to a mammal will result in systemic release of the compounds of the invention (*i.e.*, into the bloodstream). Methods of administration include enteral routes, such as oral, buccal, sublingual, and rectal; topical administration, such as transdermal and 5 intradermal; and parenteral administration. Suitable parenteral routes include injection via a hypodermic needle or catheter, for example, intravenous, intramuscular, subcutaneous, intradermal, intraperitoneal, intraarterial, intraventricular, intrathecal, intraocular and intracameral injection and non-injection routes, such as intravaginal rectal., or nasal administration. Preferably, the compounds and compositions of the invention are 10 administered orally. In specific embodiments, it may be desirable to administer one or more compounds of the invention locally to the area in need of treatment. This may be achieved, for example, by local infusion during surgery, topical application, *e.g.*, in conjunction with a wound dressing after surgery, by injection, by means of a catheter, by means of a suppository, or by means of an implant, said implant being of a porous, non-porous, or gelatinous material, 15 including membranes, such as sialastic membranes, or fibers.

The compounds of the invention can be administered via typical as well as non-standard delivery systems, *e.g.*, encapsulation in liposomes, microparticles, microcapsules, capsules, etc. For example, the compounds and compositions of the invention can be delivered in a vesicle, in particular a liposome (see Langer, 1990, *Science* 249:1527-1533; Treat *et al.*, 20 in *Liposomes in Therapy of Infectious Disease and Cancer*, Lopez-Berestein and Fidler (eds.), Liss, New York, pp. 353-365 (1989); Lopez-Berestein, *ibid.*, pp. 317-327; see generally *ibid.*). In another example, the compounds and compositions of the invention can be delivered in a controlled release system. In one embodiment, a pump may be used (see Langer, *supra*; Sefton, 1987, *CRC Crit. Ref Biomed. Eng.* 14:201; Buchwald *et al.*, 1980, 25 *Surgery* 88:507 Saudek *et al.*, 1989, *N. Engl. J Med.* 3:574). In another example, polymeric materials can be used (see *Medical Applications of Controlled Release*, Langer and Wise (eds.), CRC Press., Boca Raton, Florida (1974); *Controlled Drug Bioavailability, Drug Product Design and Performance*, Smolen and Ball (eds.), Wiley, New York (1984); Ranger and Peppas, 1983, *J. Macromol. Sci. Rev. Macromol. Chem.* 23:61; see also Levy *et* 30 *al.*, 1985, *Science* 228:190; During *et al.*, 1989, *Ann. Neurol.* 25:351; Howard *et al.*, 1989, *J. Neurosurg.* 71:105). In still another example, a controlled-release system can be placed in proximity of the target area to be treated, *e.g.*, the liver, thus requiring only a fraction of the systemic dose (see, *e.g.*, Goodson, in *Medical Applications of Controlled Release*, *supra*, vol. 2, pp. 115-138 (1984)). Other controlled-release systems discussed in the review 35 by Langer, 1990, *Science* 249:1527-1533) can be used. When administered as a composition,

a compound of the invention will be formulated with a suitable amount of a pharmaceutically acceptable vehicle or carrier so as to provide the form for proper administration to the mammal. The term "pharmaceutically acceptable" means approved by a regulatory agency of the Federal or a state government or listed in the U.S. Pharmacopeia or other generally 5 recognized pharmacopeia for use in mammals, and more particularly in humans. The term "vehicle" refers to a diluent, adjuvant, excipient, or carrier with which a compound of the invention is formulated for administration to a mammal. Such pharmaceutical vehicles can be liquids, such as water and oils, including those of petroleum, animal, vegetable or synthetic origin, such as peanut oil, soybean oil, mineral oil, sesame oil and the like. The pharmaceutical 10 vehicles can be saline, gum acacia, gelatin, starch paste, talc, keratin, colloidal silica, urea, and the like. In addition, auxiliary, stabilizing, thickening, lubricating and coloring agents may be used. Preferably, when administered to a mammal, the compounds and compositions of the invention and pharmaceutically acceptable vehicles, excipients, or diluents are sterile. An aqueous medium is a preferred vehicle when the compound of the invention is 15 administered intravenously, such as water, saline solutions, and aqueous dextrose and glycerol solutions.

The present compounds and compositions can take the form of capsules, tablets, pills, pellets, lozenges, powders, granules, syrups, elixirs, solutions, suspensions, emulsions, suppositories, or sustained-release formulations thereof, or any other form suitable for 20 administration to a mammal. In a preferred embodiment, the compounds and compositions of the invention are formulated for administration in accordance with routine procedures as a pharmaceutical composition adapted for oral or intravenous administration to humans. In one embodiment, the pharmaceutically acceptable vehicle is a hard gelatin capsule. Examples of suitable pharmaceutical vehicles and methods for formulation thereof are 25 described in Remington: The Science and Practice of Pharmacy, Alfonso R. Gennaro ed., Mack Publishing Co. Easton, PA, 19th ed., 1995, Chapters 86, 87, 88, 91, and 92, incorporated herein by reference.

Compounds and compositions of the invention formulated for oral delivery, are 30 preferably in the form of capsules, tablets, pills, or any compressed pharmaceutical form. Moreover, where in tablet or pill form, the compounds and compositions may be coated to delay disintegration and absorption in the gastrointestinal tract thereby providing a sustained action over an extended period of time. Selectively permeable membranes surrounding an osmotically active driving compound are also suitable for orally administered compounds 35 and compositions of the invention. In these later platforms, fluid from the environment surrounding the capsule is imbibed by the driving compound that swells to displace the agent

or agent composition through an aperture. These delivery platforms can provide an essentially zero order delivery profile as opposed to the spiked profiles of immediate release formulations. A time delay material such as glycerol monostearate or glycerol stearate may also be used. Oral compositions can include standard vehicles, excipients, and diluents, such as magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, lactose, dextrose, sucrose, sorbitol, mannitol, starch, gum acacia, calcium silicate, microcrystalline cellulose, polyvinylpyrrolidone, water, syrup, and methyl cellulose, the formulations can additionally include lubricating agents, such as talc, magnesium stearate, mineral oil, wetting agents, emulsifying and suspending agents, preserving agents such as methyl- and propylhydroxybenzoates. Such vehicles are preferably of pharmaceutical grade. Orally administered compounds and compositions of the invention can optionally include one or more sweetening agents, such as fructose, aspartame or saccharin; one or more flavoring agents such as peppermint, oil of wintergreen, or cherry; or one or more coloring agents to provide a pharmaceutically palatable preparation.

A therapeutically effective dosage regimen for the treatment of a particular disorder or condition will depend on its nature and severity, and can be determined by standard clinical techniques according to the judgment of a medical practitioner. In addition, *in vitro* or *in vivo* assays can be used to help identify optimal dosages. Of course, the amount of a compound of the invention that constitutes a therapeutically effective dose also depends on the administration route. In general, suitable dosage ranges for oral administration are about 0.001 milligrams to about 20 milligrams of a compound of the invention per kilogram body weight per day, preferably, about 0.7 milligrams to about 6 milligrams, more preferably, about 1.5 milligrams to about 4.5 milligrams. In a preferred embodiment, a mammal, preferably, a human is orally administered about 0.01 mg to about 1000 mg of a compound of the invention per day, more preferably, about 0.1 mg to about 300 mg per day, or about 1 mg to about 250 mg in single or divided doses. The dosage amounts described herein refer to total amounts administered; that is, if more than one compound of the invention is administered, the preferred dosages correspond to the total amount of the compounds of the invention administered. Oral compositions preferably contain 10% to 95% of a compound of the invention by weight. Preferred unit oral-dosage forms include pills, tablets, and capsules, more preferably capsules. Typically such unit-dosage forms will contain about 0.01 mg, 0.1 mg, 1 mg, 5 mg, 10 mg, 15 mg, 20 mg, 50 mg, 100 mg, 250 mg, or 500 mg of a compound of the invention, preferably, from about 5 mg to about 200 mg of compound per unit dosage.

In another embodiment, the compounds and compositions of the invention can be administered parenterally (*e.g.*, by intramuscular, intrathecal, intravenous, and intraarterial

routes), preferably, intravenously. Typically, compounds and compositions of the invention for intravenous administration are solutions in sterile isotonic aqueous vehicles, such as water, saline, Ringer's solution, or dextrose solution. Where necessary, the compositions may also include a solubilizing agent. Compositions for intravenous administration may optionally 5 include a local anesthetic such as lignocaine to ease pain at the site of the injection. For intravenous administration, the compounds and compositions of the invention can be supplied as a sterile, dry lyophilized powder or water-free concentrate in a hermetically sealed container, such as an ampule or sachette, the container indicating the quantity of active agent. Such a powder or concentrate is then diluted with an appropriate aqueous medium 10 prior to intravenous administration. An ampule of sterile water, saline solution, or other appropriate aqueous medium can be provided with the powder or concentrate for dilution prior to administration. Or the compositions can be supplied in pre-mixed form, ready for administration. Where a compound or composition of the invention is to be administered by intravenous infusion, it can be dispensed, for example, with an infusion bottle containing 15 sterile pharmaceutical-grade water, saline, or other suitable medium.

Rectal administration can be effected through the use of suppositories formulated from conventional carriers such as cocoa butter, modified vegetable oils, and other fatty bases. Suppositories can be formulated by well-known methods using well-known formulations, for example see *Remington: The Science and Practice of Pharmacy*, Alfonso 20 R. Gennaro ed., Mack Publishing Co. Easton, PA, 19th ed., 1995, pp. 1591-1597, incorporated herein by reference

To formulate and administer topical dosage forms, well-known transdermal and intradermal delivery mediums such as lotions, creams, and ointments and transdermal delivery devices such as patches can be used (Ghosh, T.K.; Pfister, W.R.; Yum, S.I. 25 *Transdermal and Topical Drug Delivery Systems*, Interpharm Press, Inc. p. 249-297, incorporated herein by reference). For example, a reservoir type patch design can comprise a backing film coated with an adhesive, and a reservoir compartment comprising a compound or composition of the invention, that is separated from the skin by a semipermeable membrane (e.g., U.S. Patent 4,615,699, incorporated herein by reference). 30 The adhesive coated backing layer extends around the reservoir's boundaries to provide a concentric seal with the skin and hold the reservoir adjacent to the skin.

The invention also provides pharmaceutical packs or kits comprising one or more containers filled with one or more compounds of the invention. Optionally associated with such container(s) can be a notice in the form prescribed by a governmental agency 35 regulating the manufacture, use or sale of pharmaceuticals or biological products, which

notice reflects approval by the agency of manufacture, use or sale for human administration. In one embodiment, the kit contains more than one compound of the invention. In another embodiment, the kit comprises a compound of the invention and another biologically active agent.

5       The compounds of the invention are preferably assayed *in vitro* and *in vivo*, for the desired therapeutic or prophylactic activity, prior to use in humans. For example, *in vitro* assays can be used to determine whether administration of a specific compound of the invention or a combination of compounds of the invention is preferred. The compounds and compositions of the invention may also be demonstrated to be effective and safe using  
10 animal model systems. Other methods will be known to the skilled artisan and are within the scope of the invention.

#### **5.8. ASSAYS USING THE METHODS OF THE INVENTION**

The methodology described above, *i.e.*, the examination of the effect of IMiDs such as Actimid<sup>TM</sup> on the differentiation on early progenitor cells, such as CD34<sup>+</sup> cells, can be applied to any compound of interest, the effect of which on differentiation is desired to be known. This may be accomplished in several ways.

In one embodiment, the compound may simply substitute for Actimid<sup>TM</sup> or any of the other compounds of the invention. Here, CD34<sup>+</sup> progenitor cells and/or CD133<sup>+</sup> progenitor cells may be contacted with the compound of interest, at varying concentrations, under conditions that allow for the proliferation and/or differentiation of the progenitor cells into committed and/or fully-differentiated cells. The culture methods disclosed herein, particularly the culture methods disclosed in Section 5.4, may be used. The effect, if any, of the compound of interest is determined by assessing the change, if any, in the cell populations that differentiate from the progenitor cells, where the change may be monitored by any phenotypic change, but is preferably assessed by determining cell surface markers that are present or absent. Like the methods of the invention, the compound of interest may be administered in a single dose at any time from initial culture to achievement of the finally-differentiated cell(s). Alternatively, the compound of interest may be administered in multiple doses during the proliferative stage, the differentiation stage, or both. The change in phenotypic characteristics of the proliferating/differentiating progenitor cells is preferably compared to a control culture of cells, such as DMSO-treated cells. Of particular interest would be any effects on proliferation or differentiation such as, but not limited to: modulation of the rate of proliferation; modulation of the rate of differentiation; modulation of differentiation of the progenitor cells into specific committed precursor cells; blocking

the differentiation into particular cell types; and enhancing the differentiation into particular cell types.

In another embodiment, culturing, proliferation and differentiation takes place as above, but the compound of interest is contacted with the progenitor cell(s) along with 5 Actimid™. In this manner, the effects, possibly synergistic, of multiple compounds may be determined. Of particular interest would be any compounds that have no, or a slight, effect on proliferation or differentiation alone, but have a significant effect in combination with Actimid™. In another embodiment, any two compounds of interest may be contacted with the progenitor cells under culture conditions, as above, that normally allow for the 10 proliferation and differentiation of the progenitor cells. Here, preferably an experiment in which precursor cells are contacted with two compounds of interest contains a control in which the progenitor cells are contacted with only one of each of said compounds; a control in which the cells are contacted with Actimid™; and a control in which cells are not contacted with a compound, or are contacted with DMSO. Again, the variations in the 15 dosages, and timing of dosing, are as described above and in Section 5.4.

## 6. WORKING EXAMPLES

### 6.1. EXAMPLE 1: Effects of Thalidomide, Actimid™ and Revimid™ on Differentiation of CD34+ Progenitor Cells

In the following example, the effects of Thalidomide (Thal), Actimid™ ("Actimid™") 20 and Revimid™ on the differentiation of CD34+ (hematopoietic progenitor) cells and the generation of colony forming units (CFU) were studied. Significantly, the results demonstrate that Actimid™ and Revimid™ can be used to suppress specifically the generation 25 of erythropoietic colonies (BFU-E and CFU-E), while augmenting both the generation of leukocyte and platelet forming colonies (CFU-GM) and enhancing total colony forming unit (CFU-Total) production.

The methods of the invention can therefore be used to regulate the differentiation of stem cells, and can also be used to stimulate the rate of colony formation, providing significant benefits to hematopoietic stem cell transplantation by improving the speed of bone marrow engraftment and recovery of leukocyte and/or platelet production.

30 Cord blood CD34+ hematopoietic progenitor cells were plated in 96 well cultivation dishes at a density of 1000 cells per well in IMDM supplemented with 20% fetal calf serum and cytokines (IL-3, G-CSF and kit-ligand (R&D Systems, Inc.) The cells were exposed to Thalidomide (Thal), Actimid™ and Revimid™, or DMSO (a control compound), and allowed to culture for 6 days. Cord blood CD34+ cells were plated in 96 well cultivation

dishes at a density of 1000 cells per well in IMDM supplemented with 20% fetal calf serum and cytokines (IL-3, GCSF and kit-ligand (KL) (R&D Systems, Inc.)) After culturing, cells were stained and sorted with a fluorescence activated cell sorter (FACS). 400 µL of stained cells were harvested and diluted to 1.0 ml with 1 % fetal calf serum in phosphate buffered saline (PBS). Cells were counted to determine the effect of modulation of stem cell differentiation. The cell counts obtained are shown in FIG. 1.

These results demonstrate that the compounds of the invention are effective in the modulation of the lineage commitment of hematopoietic progenitor stem cells. Thus, Actimid™ and Revimid™ can be used to suppress specifically the generation of red blood cells or erythropoietic colonies (BFU-E and CFU-E), while augmenting both the generation of leukocyte and platelet forming colonies (CFU-GM) and enhancing total colony forming unit production. The methods of the invention can therefore be used to regulate the differentiation of stem cells, and can also be used to stimulate the rate of specific colony formation, providing significant benefits to hematopoietic stem cell transplantation by improving the speed of bone marrow engraftment and recovery of leukocyte and/or platelet production by origin stem cell commitment toward desired engraftable lineages. Inhibition of erythropoiesis and expansion of CD34+CD38- progenitor populations by Actimid™ and Revimid™ are further represented in FIG. 2.

## 20           **6.2. EXAMPLE 2: Effects of Thalidomide, Actimid™ and Revimid™ on Proliferation and Differentiation of Human Cord Blood CD34<sup>+</sup> Cells**

In the following example, the effects of Thalidomide, Actimid™ and Revimid™ on the proliferation and differentiation of cord blood (CB) mononuclear cells into CD34+ (hematopoietic progenitor) cells were studied. Cord blood mononuclear cells are a mixed population of cells including a small population of hematopoietic progenitor (CD34+) cells. A subset of this small CD34+ cell population includes a population (approximately 1 % of total CB mononuclear cells) of CD34+CD38+ cells and an even smaller population (less than 1 % of total CB mononuclear cells) of CD34+CD38- cells. Significantly, the results demonstrate that Actimid™ causes an up-regulation (increased differentiation) of CD34+ cells, and that Actimid™ and Revimid™ can apparently inhibit or slow down the differentiation of hematopoietic stem cells or progenitor cells compared with the positive and negative controls (FIGS. 3-7).

### **6.2.1. Materials and Methods**

CB CD34+ cells were initiated at 4x10<sup>4</sup> cells/ml in a 24-well plate in 20% FCS IMDM (fetal calf serum / Iscove's Modified Dulbecco's Medium) supplemented with cytokines (IL3, GCSF and Kit-ligand) (R&D Systems, Inc.). Thalidomide (Thal), Actimid™ or

Revimid™ were included in the culture at three different concentrations: 5 µg/ml, 1 µg/ml and 0.3 µg/ml. The same volumes of DMSO were used as controls. A negative control without any compound was also used (indicated by "none" in FIGS. 3-7). Cells were cultured at 37°C and 5% CO<sub>2</sub> in a humidified incubator for 7 days. Cells were then harvested from each well.

5        The total cell number from each well was determined by counting in a CELL-DYN® 1700 (Abbott Diagnostics) and the expression of CXCR4, CD45, CD34, CD38, CD 1 lb and Gly-A expression was analyzed by FACS (fluorescence-activated cell sorting) staining (FIGS. 3-7).

10      CB cells from two different donors (CB2276 and CB2417) were cultured, assayed and analyzed separately (Table 1).

#### 6.2.2. Results and Discussion

The effects of Thalidomide, Actimid™ or Revimid™ on cytokine-stimulated expansion of CD34+ cells was tested. As shown in FIG. 4, Thalidomide, Actimid™ and Revimid™ do not have a significant effect on the proliferation of CD34+ cells that are 15 cultured in the presence of IL-3, Kit-ligand (KL) and G-CSF when compared with the negative control ("none"). However, Thalidomide, Actimid™ and Revimid™ appear to induce a yield of a slightly higher number of cells, when compared with the DMSO control. Considering that DMSO generally has a negative effect on cell proliferation in these experiments, these results suggest that Thalidomide, Actimid™ and Revimid™ compounds may have a 20 stimulatory effect on the proliferation of CD34+ cells that are cultured in the presence of IL-3, KL and G-CSF, since the same amount of DMSO is used as a carrier. In this respect, Actimid™ and Revimid™ have a greater effect than does Thalidomide.

The effects of Thalidomide, Actimid™ and Revimid™ on expression of cell differentiation were analyzed by FACS analysis of surface proteins CXCR4 and CD34 (FIGS. 3 25 and 4). Actimid™ and Revimid™, but not Thalidomide, showed an inhibitory effect upon the expression of CXCR4. Actimid™ had a more potent effect than Revimid™.

With respect to surface protein CD34+, Actimid™ caused up-regulation (increased proliferation) of CD34+ cells in both the CB2276 and CB2417 cultures. Thalidomide and Revimid™, however, exhibited a similar effect in one donor but not in the other donor. 30 Interestingly, in both Actimid™ and Revimid™ treated cells, the majority of CD34+ and CD34- cells are CD38-, while cells in the control, DMSO-treated, and Thalidomide-treated populations are mainly CD38+. This indicates that Actimid™ and Revimid™ can be used to suppress specifically the generation of red blood cells or erythropoietic colonies (BFU-E and CFU-E), while augmenting both the generation of leukocyte and platelet forming colonies 35 (CFU-GM) and enhancing total colony forming unit production. The methods of the

invention can therefore be used to regulate the differentiation of stem cells, and can also be used to stimulate the rate of colony formation, providing significant benefits to hematopoietic stem cell transplantation by improving the speed of bone marrow engraftment and recovery of leukocyte; and/or platelet production. See Table 4 below.

5 The effects of Thalidomide, Actimid™ and Revimid™ on expression of cell differentiation was analyzed by FACS analysis of surface proteins of cells that were CD34+CD38- versus CD34+CD38+ or that were CD11b+. Results are set forth in Table 1.

10 **Table 1: Examples of Effects on Cell Differentiation and Cell Surface Marker Expression of CD34, CD38 and CD11b in Cord Blood-Derived Hematopoietic Progenitor Cells**

**CD34+CD38- / CD34+CD38+ Cell Population**

**CB2276**

	None.	DMSO	Thal	Actimid™	Revimid™
5 µg/ml	1.2/6.3	2.7/3.7	3.5/6.5	17.3/0.2	
1 µg/ml	1.5/8.5	2.6/5.3	1.0/3.8	15.0/0.2	10.3/1
0.3 µg/ml	ND	1.5/5.7	3.2/15.1	5.9/0.2	9.8/1.7

**CB2417**

	None	DMSO	Thal	Actimid™	Revimid™
5 µg/ml	0.5/5.7	0.8/5.2	1.1/3.0	14.7/0.1	4.2/0.3
1 µg/ml	0.5/4.9	0.7/3.9	1.0/3.8	12.0/0.8	3.8/0.6
0.3 µg/ml	ND	0.5/4.4	0.8/5.0	5.9/0.2	3.4/0.9

**CD11b+ Cell Population**

**CB2276**

	None	DMSO	Thal	Actimid™	Revimid™
5 µg/ml	11.7%	5.0%	8.1%	1.6%	4.8%
1 µg/ml	9.1%	7.3%	6.2%	3.8%	8.6%
0.3 µg/ml	ND	7.0%	7.6%	6.9%	13.3%

**CB2417**

	None	DMSO	Thal	Actimid™	Revimid™
5 µg/ml	12.0%	7.2%	6.5%	2.5%	5.5%
1 µg/ml	7.2%	5.3%	5.2%	3.9%	8.2%
0.3 µg/ml	ND	5.1%	7.8%	8.4%	11.2%

There was no significant change in the size of the CD1 lb+ cell population, and in the case of Revimid™, a larger CD 11b+ cell population was observed at lower concentrations.

However, the level of CD1 lb expression was decreased in both Actimid™- and Revimid™- treated cells, as determined by mean immunofluorescence (MIF), indicating CD 11 b expression was repressed. This suggests that the CD11b+ cells are at a less differentiated state when cultured in the presence of Actimid™ and Revimid™.

### **6.3. EXAMPLE 3: Effects of Actimid™ and Revimid™ on Human Cord Blood MNC Cells**

In the previous examples, Actimid™ and Revimid™ were shown to significantly down-regulate the expression of CXCR4 in cord blood CD34+ cells and to increase the CD34+CD38- cell population. In this example, Actimid™ and Revimid™ are shown to have similar activities on cord blood mononucleated cells (MNC).

#### **6.3.1. Materials and Methods**

Cord blood MNCs that had been cryopreserved and thawed using standard methods were isolated by standard Ficoll separation method and cultured in 24 well-plate at  $0.5 \times 10^6$  cells/ml in 20% FCS-IMDM with cytokines (IL6, KL and G-CSF 10 ng/ml each) in triplicates. The experimental groups were None (cytokines only), DMSO (1.7 µl), Actimid™ (5.0 µg in 1.7 µl DMSO), Revimid™ (5µg in 1.7 µl DMSO). The cultured cells were harvested and analyzed by FACS staining after 1 week of culture. The results are summarized in Table 2 and in FIGS. 8-12. The data are expressed as an average +/- SD from three independent wells.

**Table 2**

	<b>None</b>	<b>DMSO</b>	<b>Actimid™</b>	<b>Revimid™</b>

#### **6.3.2. Results and Discussion**

As shown in Table 2 and in FIGS. 8-12, the total cell numbers of MNCs cultured with DMSO, Actimid™ or Revimid™ were lower than in the control group ("None," cytokines only). This may have resulted from the effects of DMSO. Cell cultures that were

cultured with MID 1 exhibited a higher percentage of CD34+ cells than all the other groups, while the total numbers of CD34+ cells were similar in all groups. Numbers of CD34+CD38- cells were significantly higher in IMJD1 and Revimid™ treated cells, which is consistent with the results of treating purified CD34+ cells with the compounds. It is well accepted that CD34+CD38- cells are a less differentiated hematopoietic progenitor cell which engrafts and proliferates after transplantation at a higher efficiency than CD34+CD38+ cells (Dao *et al.*, 1998, Blood 91 (4): 1243-55; Huang *et al.*, 1994, Blood 83(6): 1515-26).

DMSO appears to stimulate CXCR4 expression in cord blood MNCs. Actimid™ and Revimid™ significantly inhibited the expression of CXCR4 expression on CD45+ cells when compared with both control groups.

A majority of CXCR4+ cells in the cultures of Actimid™- and Revimid™-treated cells were CD45 negative. This cell population was significantly higher in the Actimid™- and Revimid™- treated cells.

The results indicate that Actimid™ and Revimid™ are useful in conditioning stem cells to counteract the deleterious effects of cryopreservation, thawing and/or exposure to cryopreservatives on stem cells. The results further indicate that the suppression by DMSO of CD34+ and CD 14+ cell production can be counteracted by treating with Actimid™ or Revimid™, which enhances the proliferative capacity of CD34+ and CD14+ cells.

**20 6.4. EXAMPLE 4: Effects of Thalidomide, Actimid™ and Revimid™ on Monocyte Production**

**6.4.1. Materials and Methods**

Purified human cord blood CD34+ cells (greater than 90%CD34+) were cultured in 20%FCS IMDM medium supplemented with cytokines (IL3, IL6, G-CSF, KL and Epo) at 4  $\times 10^4$  cells/ml for 14 days at 37°C in a humidified 5% CO<sub>2</sub> incubator. The experimental groups consisted of a group in which (i) no DMSO or chemical compounds were added ("None"), (ii) DMSO only, (iii) Thalidomide dissolved in DMSO, (iv) Actimid™ dissolved in DMSO, and (v) Revimid™ dissolved in DMSO. Aliquots of cells were harvested and stained with CD34-PE conjugated monoclonal antibody and CD14-FITC conjugated monoclonal antibody.

**6.4.2. Results and Discussion**

The results showed that in the "None" group, only 0.95% of the total cells were CD34+. In DMSO-treated group, only 0.17% of cells were CD34+, suggesting that DMSO has a negative effect on CD34+ expansion and preservation. In the Thalidomide-treated group, 0.24% of cells were CD34+, which is not significantly different from DMSO-treated

cells. In the Actimid™- and Revimid™-treated groups, however, there was a significantly higher percentage of CD34+ cells (18.7% and 7.1%, respectively). (See also experimental results depicted in FIG. 13 and accompanying figure legend).

CD14 is a marker for monocytes. In the “None” group, 11.5% of cells were CD14+, while in the DMSO-treated group, 3.7% were CD14+, indicating that the production of monocytes decreased. As was the case for CD34 expression above, the results for the Thalidomide-treated group and the DMSO-treated group were similar. Since the Actimid™- and Revimid™-treated groups were exposed to DMSO as well, it can be deduced that the monocyte production that is inhibited by DMSO is overcome by treatment with Actimid™ or Revimid™.

#### **6.5. EXAMPLE 5: Effects of Actimid™ Pretreatment on Transplanted Nucleated Cells from Umbilical Cord Blood and Placenta**

This experiment demonstrates that Actimid™ pre-treatment increases the survival of transplanted placental nucleated cells (PLNC), umbilical cord blood nucleated cells (UCBNC) and bone marrow cells (BMNC).

##### **6.5.1. Materials and Methods**

Placental nucleated cells (PLNC), umbilical cord blood nucleated cells (UCBNC) and bone marrow cells (BMNC) were obtained from human donors. PLNC and UCBNC were obtained from placenta and umbilical cord using methods described in Section 5.4 above.

The cells were pretreated by incubation in DMEM supplemented with 2% human CB serum with 10 g/ml Actimid™ for 24 hours. Cells were then washed, resuspended in autologous plasma, and administered intravenously to recipient adult SJL/L mice (Jackson Laboratories) that had bone marrow ablation produced by lethal irradiation (900cGy) according to standard methods. Such irradiation is better than 90% lethal by 50 days post-irradiation (Ende *et al.*, 2001, Life Sciences 69(13):1531-1539; Chen and Ende, 2000, J. Med. 31: 21-30; Ende *et al.*, 2000, Life Sci. 67(1):53-9; Ende and Chen, 2000, Am. J. Clin. Pathol. 114: 89).

##### **6.5.2. Results and Discussion**

The effects of Actimid™ pretreatment on the transplanted PLNC, UCBNC and BMNC are shown in Table 3 below. As can be seen in Table 3, Actimid™ pre-treatment increases the survival of transplanted placental nucleated cells (PLNC), umbilical cord blood nucleated cells (UCBNC) and bone marrow cells (BMNC).

Table 3

<b>Experimental Group</b>	<b>Treatment</b>	# of Animals Irradiated	# of Animals	Dead at 50 days	% Starting Body Weight at 50 days

5 N/A: not applicable

**6.6. Modulation of Differentiation of CD34<sup>+</sup> Progenitor Cells****6.6.1. Materials and Methods**

Bone marrow and cord blood CD34<sup>+</sup> progenitor cells were obtained from Clonetics and cultured in Iscove's MDM with BIT 95000 (StemCell Technologies) in the presence of 10 SCF, Flt-3L, GM-CSF and TNF- $\alpha$  for 6 days, and then in the presence of GM-CSF and TNF- $\alpha$  for 6 additional days.

Analysis of cell surface phenotype: Cells were processed for double staining (30 min at 4°C) at day 6 and day 12 using FITC and PE conjugated mAbs. Antibodies used were from BD Pharmingen: CD34 (PE), CD38 (FITC), CD33 (FITC), CD1a (FITC), CD86

(PE), CD14 (PE), CD83 (PE), CD54 (PE), CD11b (PE), CD11c (PE), HLA-DR (PE), CD15 (FITC), and CD133 (PE) from Miltenyi. Fluorescence analysis was performed on a FACScan flow cytometer after acquisition of 10,000 events (Coulter). Results presented are representative of four independent experiments.

5       Detection of apoptosis: Phosphatidyl serine exposure was determined using Annexin V-FITC staining in combination with propidium iodide (BD Pharmingen apoptosis detection kit I) following manufacturer instruction.

10      Phagocytosis: The endocytic activity of the cells was analyzed by measuring FITC-dextran uptake. Cells were incubated with 1 mg/ml dextran-FITC (Sigma) in complete medium at 37°C for 1 hour and 4°C for 1 hour as a negative control. Results presented are representative of two independent experiments.

15      T cell proliferation assay: After 13 days of culture, CD34<sup>+</sup>-derived DC cells were collected, and after treatment with mitomycin C (50 µg/ml, Sigma), used as stimulators cells for allogenic adult CD3<sup>+</sup> T cells purified from peripheral blood mononuclear cells (PBMCs) from healthy volunteers. CD3<sup>+</sup> T responder cells were used at a concentration of 5 x 10<sup>4</sup> cells/well. Stimulators cells were added in graded doses to the T cells in black 96-well flat bottom, clear bottom tissue culture plates for chemiluminescence detection. Cultures were performed in RPMI 1640 medium supplemented with 10% heat-inactivated FBS, glutamine and Penicillin-streptomycin. After 6 days of culture, cell proliferation was measured with 20 the BrdU chemiluminescence assay (Roche, Nutley NJ), following manufacturer instructions. Results are presented as the mean ± SD obtained from triplicate cultures.

#### 6.6.2. Results and Discussion

Actimid™ was found to significantly alter the development of DC from CD34<sup>+</sup> progenitors. To study the effect of Actimid™ on the generation of DC, CD34<sup>+</sup> progenitors 25 cells were cultured with or without Actimid™ (1 µM) for a period of 12 days during the expansion and maturation phase (day 1 to day 12), or a period of 6 days during the maturation phase (day 6 to day 12) (FIG. 14). The addition of Actimid™ from day 1 to day 12 inhibited the acquisition of the DC phenotype (FIG. 15) and more importantly increased the CD34<sup>+</sup> CD38<sup>-</sup> population, altering the normal differentiation of CD34<sup>+</sup>CD38<sup>-</sup> cells into 30 CD34<sup>+</sup>CD38<sup>+</sup> cells (FIG. 16). However, Actimid™ treated CD34<sup>+</sup> cells did acquire the CD33 myeloid marker, and these cells presented a CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> phenotype at day 6. Actimid™ almost completely prevented the generation of CD1a<sup>+</sup> cells at day 6, and particularly the generation of double positive CD86<sup>+</sup>CD1a<sup>+</sup> cells. This double positive 35 population is thought to be the precursor of epidermal Langerhans DC. Actimid™ also decreased the generation of CD14<sup>+</sup> CD1a<sup>-</sup> cells that can give rise both to dermal DC and

monocyte/ macrophages. The increase in the early progenitor population ( $CD34^+CD38^-$  cells) and the block in the myeloid DC progenitors ( $CD1a^+CD14^-$  and  $CD1a^-CD14^+$  cells) were dose dependant and reached a maximum at 1  $\mu$ M of Actimid<sup>TM</sup> (FIG. 17). This effect was reversible and interference with the CD34 differentiation pathway was only observed if 5  $CD34^+$  progenitors were cultured for at least 3 days with Actimid<sup>TM</sup> (FIG. 18).

Multiple doses of Actimid<sup>TM</sup> between days 0 and 6 intensified the increase in the  $CD34^+$  population (FIG. 19A).

10  $CD34^+$  progenitor cells cultured in the presence of Actimid<sup>TM</sup> also displayed at day 12 a decreased expression of co-stimulatory molecules (CD86, CD80) (FIG. 20). The  $CD54$  adhesion molecule was altered with decreased expression of the  $CD54^{bright}$  and increased expression of the  $CD54^{dim}$  populations (FIG. 21). The expression of HLA-DR molecules was reduced in Actimid<sup>TM</sup> treated  $CD34^+$  progenitors.

15 When Actimid<sup>TM</sup> was added at day 6, after culture from days 0-6 without treatment, and when the  $CD1a^+$  population had already been generated, Actimid<sup>TM</sup> increased the persistence of the  $CD1a^+$  population (Table 1). The Actimid<sup>TM</sup> -treated culture contained relatively more  $CD1a^+$  precursors at day 12 than the DMSO control. The addition of Actimid<sup>TM</sup> to day 6  $CD34^+$  differentiated cells also decreased considerably the generation of  $CD14^+$  precursors and the expression of the co-stimulatory molecules (CD86, CD80).

20 Table 1. Phenotypic characterization at day 12 of DC generated from  $CD34^+$  progenitor cells in the presence of Actimid<sup>TM</sup> from day 6 to day 12

Day 12	DMSO day 6 to day 12	Actimid <sup>TM</sup> day 6 to day 12
CD1a+	8.5 %	11.5 %
CD14+	19.0 %	8.0 %
CD86+	28.8 %	18.5 %
CD80+	19.6 %	13.8 %

25 Actimid<sup>TM</sup> promotes granulocytic differentiation: To determine if the block in DC generation was associated with a change to a different myeloid differentiation pathway, we monitored the expression of the CD15 granulocytic marker. Expression of the CD15 surface molecule was increased in  $CD34^+$  progenitor cells cultured in the presence of Actimid<sup>TM</sup> (FIG. 22). In the presence of a cytokine cocktail that drives DC differentiation, the addition of Actimid<sup>TM</sup> diverted the expansion/maturation of progenitor cells into a more granulocyte-like phenotype. We also studied the skew in myeloid differentiation by 30 monitoring the expression of 2 markers: CD11c, expressed by myeloid DC progenitors for Langerhans cells and interstitial DC, and CD15 expressed by granulocyte progenitors. A decrease in the  $CD11c^+CD15^-$  population was associated with a concomitant increase in

the CD11c<sup>-</sup>CD15<sup>+</sup> granulocytic population (FIG. 19B). Interestingly, multiples doses of Actimid™ enhanced the shift towards the granulocytic lineage.

Block in DC generation is not mediated by specific killing of the DC progenitors: To determine if the decrease in DC progenitors was mediated by specific killing, CD34<sup>+</sup> 5 progenitor cells were cultured for a period of 6 days in the presence of SCF, Flt-3L, GM-CSF and TNF- $\alpha$ . At day 6, CD1a<sup>+</sup>CD14<sup>-</sup> and CD1a<sup>+</sup>CD14<sup>+</sup> cells (DC progenitors) were isolated by magnetic cell sorting (Miltenyi). Purified populations were cultured for an additional 2 days in the presence of GM-CSF and TNF- $\alpha$  with or without Actimid™ (1  $\mu$ M). There was no significant increase in the level of annexin V<sup>+</sup>- PI<sup>-</sup> (early apoptosis) and 10 annexin V<sup>+</sup>- PI<sup>+</sup> (late apoptosis) populations upon Actimid™ treatment (FIG. 23).

Functional activity of DC generated from CD34<sup>+</sup> progenitors is altered: The phagocytic capacity of cells derived from CD34<sup>+</sup> progenitors cells cultured with cytokines with or without Actimid™ was assayed by the mannose receptor-mediated endocytosis of dextran-FITC at day 12. When Actimid™ was added from day 1 to day 12, there was a 15 strong decrease in the phagocytic capacity compared to DMSO control (FIG. 24). When Actimid™ was added from day 6 to day 12 the phagocytic capacity was comparable to the DMSO-control cells (FIG. 25).

The antigen presentation capacity (APC) of CD34<sup>+</sup> cells cultured with cytokine with or without Actimid™ was evaluated by measuring their capacity to induce the proliferation 20 of CD3<sup>+</sup> allogenic T cells in a Mixed Leucocyte Reaction (MLR) assay at day 12. When Actimid™ was added from day 1 to day 12, the CD34<sup>+</sup> cells showed a reduced capacity to stimulate the proliferation of T-cells as compared to DMSO control (FIG. 26). In contrast, when Actimid™ was added from day 6 to day 12, the capacity to stimulate the proliferation 25 of T-cells was comparable to the DMSO-control cells (FIG. 27). The normal differentiation pathway followed by CD34<sup>+</sup> cells is depicted in FIG. 28.

These results indicate that Actimid™ dramatically attenuated the differentiation of CD34<sup>+</sup> progenitor cells into dendritic cells. As a consequence, Actimid™ treated cells presented a low phagocytic capacity and a reduced APC capacity. More importantly, 30 Actimid™ increased early hematopoietic progenitors, the CD34<sup>+</sup>CD38<sup>-</sup> cells. Those early hematopoietic progenitors have been shown to give better engraftment and repopulation in the NOD-SCID mouse model (Tamaki *et al.*, J. Neurosci. Res. 69(6):976-86 (2002)). Moreover, Actimid™ skewed CD34<sup>+</sup> cells differentiation by switching myeloid 35 differentiation toward the granulocytic lineage, even when the cytokine pressure is in favor of dendritic cell differentiation. In addition, Actimid™ was found to have no toxic effects on CD34<sup>+</sup> cells, and not to impair the cells' ability to proliferate. This modulation of DC

function and promotion of granulocytic differentiation can have significant therapeutic utility for the treatment of various cancers, immunological disorders, and infectious diseases, and in organ transplants, and regenerative medicine.

See FIG. 29 for a graphical summary of the above.

5           **6.7. Actimid<sup>TM</sup> Modulates Differentiation of CD133<sup>+</sup> Progenitor Cells**

Multiple doses of Actimid<sup>TM</sup>, in addition to intensifying the increase in the CD34<sup>+</sup> population, also increases the expression of CD133, which is usually expressed by CD34<sup>bright</sup> hematopoietic progenitor cells and some primitive CD34<sup>-</sup> subpopulations (FIGS 19A, 19B). Actimid<sup>TM</sup>, by enriching for the CD34<sup>+</sup>CD133<sup>+</sup> primitive hematopoietic cells, 10 should have clinical implication for hematopoietic recovery after stem cell transplantation. In addition, CD133<sup>+</sup> stem cells can also give rise to the endothelial lineage and contribute in term to wound healing. Multiple doses of Actimid<sup>TM</sup> did not exacerbate the block in the generation of Langerhans DC precursors.

15           **6.8. Generation of Murine Dendritic cells from Bone Marrow (BM) Sca<sup>+</sup> Hematopoietic Progenitor Cells**

**6.8.1. Materials and Methods**

Mouse bone marrow from inbred C57BL/6 mice was obtained from Clonetics. Hematopoietic Sca<sup>+</sup>Lin- progenitors were enriched using SpinSep murine progenitor enrichment cocktail (StemCell Technologies) and cultured in Iscove's MDM with BIT 20 95000 (StemCell Technologies) in the presence of murine growth factors SCF, Flt3L, GM-CSF and M-CSF for 9 days, to promote expansion of Sca<sup>+</sup> cells and a DC precursor phenotype and then in the presence of GM-CSF and TNF- $\alpha$  for 3 additional days to drive the cells to an immature DC phenotype. See FIG. 30. Enriched Sca<sup>+</sup>Lin- cells were cultured in the presence of DMSO (0.1%), Actimid<sup>TM</sup> at 10  $\mu$ M or all-trans retinoic acid 25 (ATRA) (ICN Biomedicals) at 10  $\mu$ M from day 0. Compounds were added to cells at day 0 and day 9.

Analysis of Murine cell surface phenotype: Murine cells were processed for double staining (14 min at RT) at day 9 and day 12; using FITC and PE conjugated mAbs.

Antibodies used were from BD Pharmingen: Sca (PE), CD11b (FITC), Gr-1 (FITC), CD86

30 (PE), CD14 (PE), CD80 (PE), I-A<sup>b</sup> (PE), CD40 (PE) and CD32.1/16.1 (FITC) from Miltenyi. Fluorescence analysis was performed on a FACScan flow cytometer (Coulter) after acquisition of 10,000 events.

### 6.8.2. Results and Discussion

Actimid<sup>TM</sup> was found to alter the development of Murine DC from Sca<sup>+</sup> progenitors.

At day 9 cells presented a DC precursor phenotype with high surface expression of dendritic/ myeloid markers CD32/16 (Fc receptors), CD11b, CD80, low expression of I-A<sup>b</sup> and CD86, and lack of expression of lineage markers as CD14 and Gr-1 (FIG. 31).

Actimid<sup>TM</sup> showed no significant effect on cell surface marker expression by day 9 while ATRA showed marked downregulation of CD80, I-A<sup>b</sup> and Sca+ expression (data not shown). However by day 12, Actimid<sup>TM</sup> showed downregulation of CD86 and bright I-A<sup>b</sup> expression and upregulation of CD11b expression (FIG. 32). ATRA showed similar but 10 more pronounced effects than Actimid<sup>TM</sup>. In addition, Actimid<sup>TM</sup> showed no effects on the expression of CD40 and CD80 while ATRA showed marked downregulation of these molecules (not shown).

These results suggest that Actimid<sup>TM</sup> inhibits the differentiation of DC precursors into immature DC by downregulating CD86 and MHC II expression. The compound's 15 effects are not as dramatic as those observed in human hematopoietic progenitors and this parallels the low activity of Actimid<sup>TM</sup> in mouse in vitro and in vivo in other models. The effect of Actimid<sup>TM</sup> is much less pronounced than that of ATRA, which is a teratogen in mice.

### 6.9. Application of Differentiation Assay to Compounds Other Than IMiDs

The methodology described above, *i.e.*, the examination of the effect of IMiDs such 20 as Actimid<sup>TM</sup> on the differentiation on early progenitor cells, such as CD34<sup>+</sup> cells, can be applied to any compound of interest, the effect of which on differentiation is desired to be known. As an example of the extension of this assay method to other compounds, we compared the effect of retinoic acid (ATRA) and aspirin to that of Actimid<sup>TM</sup> on the 25 differentiation of CD34<sup>+</sup> cells toward the DC lineage versus the control (DMSO-treated) cells. Retinoic acid was studied because of its known effect on cellular proliferation and differentiation, its therapeutic use in some cancer, and its known teratogenic effect. Conversely, we studied the effect of aspirin because it is a commonly-used anti-inflammatory drug with no immunomodulatory properties. The results at day 6 of CD34<sup>+</sup> 30 progenitors cells cultured in the presence of SCF, Flt-3L, GM-CSF and TNF- $\alpha$ , with or without compound for a period of 6 days, are presented below in Table 2 (up arrow indicates an increase in the cell population; down arrow indicates a decrease).

Table 2. Comparison of effect of Actimid<sup>TM</sup>, retinoic acid, and aspirin on CD34<sup>+</sup> progenitor cell differentiation.

Cell Population	Actimid <sup>TM</sup>	All-trans RA	Aspirin
CD34 <sup>+</sup> CD38 <sup>-</sup>	↑	↓	No change
CD34 <sup>+</sup> CD38 <sup>+</sup>	↓	↑	No change
CD1a <sup>+</sup> CD14 <sup>-</sup>	↓	↓	No change
CD1a <sup>-</sup> CD14 <sup>+</sup>	↓	↓	No change
CD15 <sup>+</sup>	↑	↑	No change

In the literature other drugs have been shown to modulate cellular differentiation, for example, a recent paper reports the modulation by corticosteroids of DC generation from CD34<sup>+</sup> progenitors cells. The profile differs from Actimid<sup>TM</sup> with an increase in the CD1a<sup>+</sup> population and a decrease in the CD14<sup>+</sup> population.

#### 6.10. EXAMPLE 10: Induction of Differentiation into Particular Cell Types

Cord blood cells and/or embryonic-like stem cells are induced to differentiate into a particular cell type by exposure to a growth factor. Growth factors that are used to induce induction include, but are not limited to: GM-CSF, IL-4, Flt3L, CD40L, IFN-alpha, TNF-alpha, IFN-gamma, IL-2, IL-6, retinoic acid, basic fibroblast growth factor, TGF-beta-1, TGF-beta-3, hepatocyte growth factor, epidermal growth factor, cardiotropin-1, angiotensinogen, angiotensin I (AI), angiotensin II (AII), AII AT<sub>2</sub> type 2 receptor agonists, or analogs or fragments thereof.

##### 6.10.1. Induction Of Differentiation Into Neurons

This example describes the induction of cord blood cells and/or embryonic-like stem cells to differentiate into neurons. The following protocol is employed to induce neuronal differentiation:

- 20 1. Placental stem cells are grown for 24 hr in preinduction media consisting of DMEM/20% FBS and 1 mM beta-mercaptoethanol.
2. Preinduction media is removed and cells are washed with PBS.
3. Neuronal induction media consisting of DMEM and 1-10 mM betamercaptoethanol is added. Alternatively, induction media consisting of DMEM/2% DMSO/200 µM butylated hydroxyanisole may be used to enhance neuronal differentiation efficiency.
4. In certain embodiments, morphologic and molecular changes may occur as early as 60 minutes after exposure to serum-free media and betamercaptoethanol (Woodbury et al., J. Neurosci. Res., 61:364-370). RT/PCR may be used to assess the expression of e.g., nerve growth factor receptor and neurofilament heavy chain genes.

### 6.10.2. Induction Of Differentiation Into Adipocytes

This example describes the induction of cord blood cells and/or embryonic-like stem cells to differentiate into adipocytes. The following protocol is employed to induce adipogenic differentiation:

- 5      1. Placental stem cells are grown in MSCGM (Bio Whittaker) or DMEM supplemented with 15% cord blood serum.
2. Three cycles of induction/maintenance are used. Each cycle consists of feeding the placental stem cells with Adipogenesis Induction Medium (Bio Whittaker) and culturing the cells for 3 days (at 37°C, 5% CO<sub>2</sub>), followed by 1-3 days of culture in
- 10     Adipogenesis Maintenance Medium (Bio Whittaker). An induction medium is used that contains 1 µM dexamethasone, 0.2 mM indomethacin, 0.01 mg/ml insulin, 0.5 mM IBMX, DMEM-high glucose, FBS, and antibiotics.
- 15     3. After 3 complete cycles of induction/maintenance, the cells are cultured for an additional 7 days in adipogenesis maintenance medium, replacing the medium every 2-3 days.
- 20     4. Adipogenesis may be assessed by the development of multiple intracytoplasmic lipid vesicles that can be easily observed using the lipophilic stain oil red O. RT/PCR assays are employed to examine the expression of lipase and fatty acid binding protein genes.

### 6.10.3. Induction Of Differentiation Into Chondrocytes

This example describes the induction of cord blood cells and/or embryonic-like stem cells to differentiate into chondrocytes. The following protocol is employed to induce chondrogenic differentiation:

- 25     1. Placental stem cells are maintained in MSCGM (Bio Whittaker) or DMEM supplemented with 15% cord blood serum.
2. Placental stem cells are aliquoted into a sterile polypropylene tube. The cells are centrifuged (150 x g for 5 minutes), and washed twice in Incomplete Chondrogenesis Medium (Bio Whittaker).
- 30     3. After the last wash, the cells are resuspended in Complete Chondrogenesis Medium (Bio Whittaker) containing 0.01 µg/ml TGF-beta-3 at a concentration of 5 x 10(5) cells/ml.
- 35     4. 0.5 ml of cells is aliquoted into a 15 ml polypropylene culture tube. The cells are pelleted at 150 x g for 5 minutes. The pellet is left intact in the medium.
5. Loosely capped tubes are incubated at 37°C, 5% CO<sub>2</sub> for 24 hours.
- 35     6. The cell pellets are fed every 2-3 days with freshly prepared complete chondrogenesis medium.
7. Pellets are maintained suspended in medium by daily agitation using a low speed vortex.

8. Chondrogenic cell pellets are harvested after 14-28 days in culture.
9. Chondrogenesis may be characterized by *e.g.*, observation of production of esoinophilic ground substance, assessing cell morphology, an/or RT/PCR for examining collagen 2 and collagen 9 gene expression.

5

#### **6.10.4. Induction Of Differentiation Into Osteocytes**

This example describes the induction of cord blood cells and/or embryonic-like stem cells to differentiate into osteocytes. The following protocol is employed to induce osteogenic differentiation:

1. Adherent cultures of placental stem cells are cultured in MSCGM (Bio Whittaker) or DMEM supplemented with 15% cord blood serum.
2. Cultures are rested for 24 hours in tissue culture flasks.
3. Osteogenic differentiation is induced by replacing MSCGM with Osteogenic Induction Medium (Bio Whittaker) containing 0.1  $\mu$ M dexamethasone, 0.05 mM ascorbic acid-2-phosphate, 10 mM beta glycerophosphate.
4. Cells are fed every 3-4 days for 2-3 weeks with Osteogenic Induction Medium.
5. Differentiation is assayed using a calcium-specific stain and RT/PCR for alkaline phosphatase and osteopontin gene expression.

#### **6.10.5. Induction Of Differentiation Into Hepatocytes**

This example describes the induction of cord blood cells and/or embryonic-like stem cells to differentiate into hepatocytes. The following protocol is employed to induce hepatogenic differentiation:

1. Placental stem cells are cultured in DMEM/20% CBS supplemented with hepatocyte growth factor, 20 ng/ml; and epidermal growth factor, 100 ng/ml. KnockOut Serum Replacement may be used in lieu of FBS.
2. IL-6 50 ng/ml is added to induction flasks.

#### **6.10.6. Induction Of Differentiation Into Pancreatic Cells**

This example describes the induction of cord blood cells and/or embryonic-like stem cells to differentiate into pancreatic cells. The following protocol is employed to induce pancreatic differentiation:

30. 1. Placental stem cells are cultured in DMEM/20% CBS, supplemented with basic fibroblast growth factor, 10 ng/ml; and transforming growth factor beta-1, 2 ng/ml. KnockOut Serum Replacement may be used in lieu of CBS.
2. Conditioned media from nestin-positive neuronal cell cultures is added to media at a 50/50 concentration.

3. Cells are cultured for 14-28 days, refeeding every 3-4 days.
4. Differentiation is characterized by assaying for insulin protein or insulin gene expression by RT/PCR.

#### **6.10.7. Induction Of Differentiation Into Cardiac Cells**

5 This example describes the induction of cord blood cells and/or embryonic-like stem cells to differentiate into cardiac cells. The following protocol is employed to induce myogenic differentiation:

1. Placental stem cells are cultured in DMEM/20% CBS, supplemented with retinoic acid, 1  $\mu$ M; basic fibroblast growth factor, 10 ng/ml; and transforming growth factor beta-1, 2 ng/ml; and epidermal growth factor, 100 ng/ml. KnockOut Serum Replacement may be used in lieu of CBS.
- 10 2. Alternatively, placental stem cells are cultured in DMEM/20% CBS supplemented with 50 ng/ml Cardiotropin-1 for 24 hours.
3. Alternatively, placental stem cells are maintained in protein-free media for 5-7 days, then stimulated with human myocardium extract (escalating dose analysis). Myocardium extract is produced by homogenizing 1 gm human myocardium in 1% HEPES buffer supplemented with 1% cord blood serum. The suspension is incubated for 60 minutes, then centrifuged and the supernatant collected.
- 15 4. Cells are cultured for 10-14 days, refeeding every 3-4 days.
- 20 5. Differentiation is assessed using cardiac actin RT/PCR gene expression assays.

#### **6.10.8. Characterization of Cord Blood Cells and/or Embryonic-Like Stem Cells Prior to and/or After Differentiation**

The embryonic-like stem cells, the cord blood cells and/or the populations of cord blood cells spiked with embryonic-like stem cells are characterized prior to and/or after differentiation by measuring changes in morphology and cell surface markers using techniques such as flow cytometry and immunocytochemistry, and measuring changes in gene expression using techniques, such as PCR. Cells that have been exposed to growth factors and/or that have differentiated are characterized by the presence or absence of the following cell surface markers: CD10+, CD29+, CD34-, CD38-, CD44+, CD45-, CD54+, CD90+, SH2+, SH3+, SH4+, SSEA3-, SSEA4-, OCT-4+, and ABC-p+. Preferably, the embryonic-like stem cell are characterized, prior to differentiation, by the presence of cell surface markers OCT-4+, APC-p+, CD34- and CD38-. Stem cells bearing these markers are as versatile (*e.g.*, pluripotent) as human embryonic stem cells. Cord blood cells are characterized, prior to differentiation, by the presence of cell surface markers CD34+ and CD38+. Differentiated cells derived from embryonic-like stem cells, cord blood cells

and/or a populations of cord blood cells spiked with embryonic-like stem cells preferably do not express these markers.

5        The present invention is not to be limited in scope by the specific embodiments described herein. Indeed, various modifications of the invention in addition to those described herein will become apparent to those skilled in the art from the foregoing description. Such modifications are intended to fall within the scope of the appended claims.

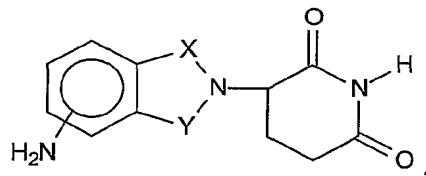

## 7. LITERATURE

10       All references cited herein are incorporated herein by reference in their entirety and for all purposes to the same extent as if each individual publication, patent or patent application was specifically and individually indicated to be incorporated by reference in its entirety for all purposes.

15       The citation of any publication is for its disclosure prior to the filing date and should not be construed as an admission that the present invention is not entitled to antedate such publication by virtue of prior invention.

WHAT IS CLAIMED:

1. A method for modulating the differentiation of a mammalian stem cell comprising differentiating said stem cell under suitable conditions and in the presence of a compound that inhibits TNF- $\alpha$  activity, wherein said compound is not a polypeptide, peptide, protein, hormone, cytokine, oligonucleotide, or nucleic acid.
2. The method of claim 1 wherein said stem cell is differentiated into a hematopoietic cell.
3. The method of claim 1 wherein said stem cell is selected from the group consisting of an embryonic stem cell, a placental stem cell, a cord blood stem cell, a peripheral blood stem cell, and a bone marrow stem cell.
4. The method of claim 1, wherein said compound is an amino-substituted thalidomide analog or amino-substituted isoindoline.
5. The method of claim 4, wherein said amino-substituted thalidomide analog or amino-substituted isoindoline is selected from the group consisting of Actimid™, Revimid™, an analog or prodrug of Actimid™, an analog or prodrug of Revimid™, and a compound of the formula:

wherein one of  $\text{X}$  and  $\text{Y}$  is  $\text{C=O}$  and the other of  $\text{X}$  and  $\text{Y}$  is  $\text{C=O}$  or  $\text{CH}_2$ .

6. The method of claim 4, wherein said amino-substituted thalidomide is selected from the group consisting of 1-oxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline, 1-oxo-2-(2,6-dioxopiperidin-3-yl)-4-aminoisoindoline, 1-oxo-2-(2,6-dioxopiperidin-3-yl)-6-aminoisoindoline, 1-oxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline, 1,3dioxo-2-(2,6-dioxopiperidin-3-yl)-4-aminoisoindoline, and 1,3dioxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline.
7. The method of claim 1 wherein the contacting step is conducted in cell culture.
8. The method of claim 1, wherein said contacting step is conducted within said individual.
9. The method of claim 1 wherein the concentration of the compound is from about 0.005  $\mu\text{g}/\text{ml}$  to about 5 mg/ml.
10. The method of claim 1 wherein the stem cell is a human stem cell.
11. A method for modulating the proliferation or differentiation of a mammalian  $\text{CD34}^+$  or  $\text{CD133}^+$  progenitor cell comprising proliferating or differentiating said cell under

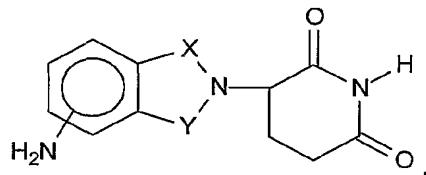

conditions suitable for proliferation or differentiation and in the presence of a compound that inhibits TNF- $\alpha$  activity, wherein said compound is not a polypeptide, peptide, protein, hormone, cytokine, oligonucleotide, or nucleic acid.

12. The method of claim 11, wherein said progenitor cell is selected from the group consisting of a CD34 $^{+}$  progenitor cell and a CD133 $^{+}$  progenitor cell.

13. The method of claim 11, wherein said progenitor cells differentiate into CD34 $^{+}$ CD38–CD33 $^{+}$  or CD34 $^{+}$ CD38–CD33– cells.

14. The method of claim 11, wherein said compound analog is an amino-substituted thalidomide analog or amino-substituted isoindoline.

15. The method of claim 11, wherein said compound is selected from the group consisting of Actimid<sup>TM</sup>, Revimid<sup>TM</sup>, an analog or prodrug of Actimid<sup>TM</sup>, an analog or prodrug of Revimid<sup>TM</sup>, and a compound of the formula

wherein one of X and Y is C=O and the other of X and Y is C=O or CH<sub>2</sub>.

16. The method of claim 11, wherein said compound is selected from the group consisting of 1-oxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline, 1-oxo-2-(2,6-dioxopiperidin-3-yl)-4-aminoisoindoline, 1-oxo-2-(2,6-dioxopiperidin-3-yl)-6-aminoisoindoline, 1-oxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline, 1,3dioxo-2-(2,6-dioxopiperidin-3-yl)-4-aminoisoindoline, and 1,3dioxo-2-(2,6-dioxopiperidin-3-yl)-5-aminoisoindoline.

17. The method of claim 11 wherein the contacting step is conducted in cell culture.

18. The method of claim 11, wherein said contacting step is conducted within an individual.

19. The method of claim 17, wherein said progenitor cells are cells that have been transplanted into said individual.

20. The method of claim 11, wherein said contacting is sufficient to cause a detectable difference in differentiation or proliferation relative to a control.

21. The method of claim 11, wherein said CD34 $^{+}$  or CD133 $^{+}$  progenitor cell has been cryopreserved and thawed prior to said differentiating.

22. A method for modulating the differentiation of a CD34 $^{+}$  or CD133 $^{+}$  progenitor cell comprising:

- (a) providing a population of said progenitor cells under conditions such that differentiation can occur;
- (b) contacting said progenitor cells with a compound, wherein said compound is an amino-substituted thalidomide analog or amino-substituted isoindoline; and
- (c) differentiating said progenitor cells under conditions suitable for differentiation, wherein said compound is placed in contact with said progenitor cells for at least part of the time said progenitor cells are differentiating.

23. The method of claim 22, wherein in step (b), said contacting is performed at any time between day 0 to day 6 of culture.

24. The method of claim 22, wherein in step (b), said contacting is performed at the start of the culture of said progenitor cells.

25. The method of claim 22, wherein in step (b), said contacting is performed after said progenitor cells have proliferated for at least two days.

26. The method of claim 22, wherein in step (b), said contacting is performed after said progenitor cells have proliferated for at least six days.

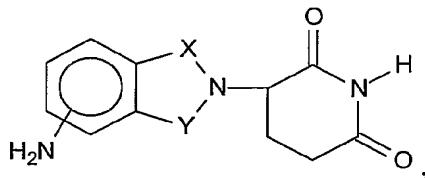

27. The method of claim 22, wherein said progenitor cells are CD34<sup>+</sup> progenitor cells.

28. The method of claim 22, wherein said progenitor cells differentiate into cells exhibiting cell surface marker characteristics selected from the group consisting of:

- a decrease in CD11c expression relative to a control;
- a decrease in CD38 expression relative to a control;
- a decrease in CD80 expression relative to a control;
- a decrease in CD86 expression relative to a control;
- a decrease in CD1a expression relative to a control;
- a decrease in CD14 expression relative to a control;
- a decrease in CD54<sup>bright</sup> expression relative to a control;
- a decrease in HLA-DR expression relative to a control;
- an increase in CD15 expression relative to a control;
- an increase in CD33 expression relative to a control;
- an increase in CD54<sup>dim</sup> expression relative to a control;
- an increase in CD133 expression relative to a control; and
- a combination of any of the above marker characteristics;

wherein said control is a CD34<sup>+</sup> progenitor cell cultured under the same conditions as said progenitor cell in the absence of said compound.

29. The method of claim 22, wherein said progenitor cells differentiate into CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> cells.
30. The method of claim 22, wherein said thalidomide analog is Actimid<sup>TM</sup> or Revimid<sup>TM</sup>.
31. A method for expanding a progenitor cell population in a mammalian subject, comprising administering a therapeutically effective amount of CD34<sup>+</sup> progenitor cells and a compound that inhibits TNF- $\alpha$  activity to said mammalian subject, wherein said compound is not a polypeptide, peptide, protein, hormone, cytokine, oligonucleotide, or nucleic acid
32. The method of claim 31 wherein said CD34<sup>+</sup> progenitor cells are differentiated in said mammalian subject.
33. The method of claim 31 wherein said CD34<sup>+</sup> progenitor cells are administered to said mammalian subject in a cell preparation that is substantially free of red blood cells.
34. The method of claim 31 wherein said CD34<sup>+</sup> progenitor cells are administered to said mammalian subject in a cell preparation that comprises bone marrow cells, placental cells, or cord blood cells.
35. The method of claim 31 wherein said CD34<sup>+</sup> progenitor cells are administered to said mammalian subject in conjunction with a carrier.
36. The method of claim 31 wherein said CD34<sup>+</sup> progenitor cells are CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>+</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD33<sup>-</sup> progenitor cells.
37. The method of claim 31 wherein said CD34<sup>+</sup> cell is a CD34<sup>+</sup>CD133<sup>+</sup> progenitor cell.
38. The method of claim 31 wherein the progenitor cells express incorporated genetic material of interest.
39. A pharmaceutical composition comprising a mammalian stem cell and a pharmaceutically-acceptable carrier, wherein said stem cell has been contacted with a compound that inhibits TNF- $\alpha$  activity for a time sufficient to cause modulation of differentiation or proliferation of said stem cell, and wherein said compound is not a polypeptide, peptide, protein, hormone, cytokine, oligonucleotide, or nucleic acid.
40. The pharmaceutical composition of claim 39 wherein the stem cell is selected from the group consisting of an embryonic stem cell, a placental stem cell, a cord blood stem cell, a peripheral blood stem cell, and a bone marrow stem cell.
41. The pharmaceutical composition of claim 39 wherein said compound is selected from the group consisting of Actimid<sup>TM</sup>, Revimid<sup>TM</sup>, an analog of Actimid<sup>TM</sup>, an analog of Revimid<sup>TM</sup>, and a compound of the formula

wherein one of X and Y is C=O and the other of X and Y is C=O or CH<sub>2</sub>,

42. The pharmaceutical composition of claim 39 wherein said contacting step is conducted in cell culture.

43. The pharmaceutical composition of claim 39 wherein the concentration of said compound is from about 0.005 mg/ml to about 5 mg/ml.

44. The pharmaceutical composition of claim 39 wherein the stem cell is a human stem cell.

45. The pharmaceutical composition of claim 39 wherein the differentiation is differentiation into a hematopoietic cell.

46. The pharmaceutical composition of claim 45 wherein said hematopoietic cell is a CD34+ or CD38+ hematopoietic cell.

47. The pharmaceutical composition of claim 45 wherein the hematopoietic cell is a CD11b+ cell.

48. A pharmaceutical composition comprising isolated cord blood cells and an isolated population of white blood cells, wherein the white blood cells are generated by a method comprising differentiating stem cells under suitable conditions and in the presence of a compound that inhibits TNF- $\alpha$  activity, with the proviso that the compound is not a polypeptide, peptide, protein, hormone, cytokine, oligonucleotide, or nucleic acid, and isolating the white blood cells differentiated thereby.

49. The pharmaceutical composition of claim 48 wherein the compound is an imide or amide.

50. The pharmaceutical composition of claim 48 wherein the differentiating step is conducted in cell culture.

51. The pharmaceutical composition of claim 48 wherein the concentration of the compound is from about 0.005  $\mu$ g/ml to about 5 mg/ml.

52. The pharmaceutical composition of claim 48 wherein the stem cell is a human stem cell.

53. The pharmaceutical composition of claim 48 wherein the stem cell is a progenitor cell.

54. The pharmaceutical composition of claim 53 wherein the progenitor cell is committed to a specific cell lineage.

55. The pharmaceutical composition of claim 54 wherein the progenitor cell is a hematopoietic progenitor cell.

56. A pharmaceutical composition comprising cultured CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells and a pharmaceutically-acceptable carrier, wherein said progenitor cells have been contacted within the first six days of culture with a compound that inhibits the activity of TNF- $\alpha$ , under conditions that promote proliferation and differentiation of said progenitor cells.

57. The pharmaceutical composition of claim 56 wherein said progenitor cells are collected and cryopreserved after six days of culture.

58. The pharmaceutical composition of claim 56 wherein said progenitor cells are CD34<sup>+</sup>CD38<sup>-</sup>CD34<sup>-</sup> or CD34<sup>+</sup>CD38<sup>-</sup>CD34<sup>+</sup> cells.

59. The pharmaceutical composition of claim 56 wherein said compound is thalidomide or a thalidomide analog.

60. The pharmaceutical composition of claim 56 in which said compound is Actimid<sup>TM</sup> or Revimid<sup>TM</sup>.

61. A method of transplanting a mammalian stem cell comprising:

(a) contacting said stem cell with thalidomide or a thalidomide analog to produce a treated stem cell, wherein said contacting is sufficient to modulate the differentiation of said stem cell; and

(b) administering said treated stem cell to an individual.

62. The method of claim 61, wherein step (b) comprises administering said treated stem cell in combination with untreated cells.

63. The method of claim 61 wherein the untreated cell is selected from the group consisting of an embryonic stem cell, a placental cell, a cord blood cell, a peripheral blood cell, and a bone marrow cell.

64. The method of claim 61, wherein said stem cell has been cryopreserved and thawed prior to said administering.

65. A method of transplanting a mammalian progenitor cell comprising:

(a) contacting said progenitor cell with thalidomide or a thalidomide analog to produce a treated progenitor cell, wherein said contacting is sufficient to modulate the differentiation of said progenitor cell; and

(b) administering said treated progenitor cell to an individual.

66. The method of claim 65, wherein step (b) comprises administering said treated progenitor cell in combination with untreated cells.

67. The method of claim 65 wherein the untreated cell is selected from the group consisting of an embryonic stem cell, a placental cell, a cord blood cell, a peripheral blood cell, and a bone marrow cell.

68. The method of claim 65, wherein said stem cell has been cryopreserved and thawed prior to said administering.

69. A method of treating an individual experiencing a condition comprising administering to said individual an agent selected from the group consisting of:

(a) a compound that inhibits TNF- $\alpha$  activity for a time sufficient to cause modulation of differentiation or proliferation of said stem cell, and wherein said compound is not a polypeptide, peptide, protein, hormone, cytokine, oligonucleotide, or nucleic acid;

(b) a stem cell differentiated in the presence of said compound; and

(c) a progenitor cell differentiated in the presence of said compound, wherein said agent detectably reduces or ameliorates said condition.

70. The method of claim 69, wherein said condition is inflammation.

71. A method for treating an individual comprising administering a therapeutically effective amount of white blood cells to said recipient mammalian subject, wherein said white blood cells are generated by a method comprising differentiating a stem cell under suitable conditions and in the presence of a compound that inhibits TNF- $\alpha$  activity, with the proviso that the compound is not a polypeptide, peptide, protein, hormone, cytokine, oligonucleotide, or nucleic acid.

72. The method of claim 71 wherein the stem cells are differentiated *in vitro*.

73. The method of claim 71 wherein the stem cells are differentiated in a postpartum perfused placenta.

74. The method of claim 71 wherein the white blood cells are administered to the individual in a cell preparation that is substantially free of red blood cells.

75. The method of claim 71 wherein the white blood cells are administered to the individual in a cell preparation which comprises cord blood cells.

76. The method of claim 71 wherein the white blood cells are administered to the individual in conjunction with a carrier.

77. The method of claim 71 wherein the white blood cells are administered to treat or repair a defect in the recipient mammalian subject.

78. The method of claim 77 wherein the defect is a hematopoietic or blood cell proliferation defect.

79. The method of claim 77 wherein the hematopoietic or blood cell proliferation defect is neutropenia or leukopenia.

80. The method of claim 77 wherein the white blood cells are administered systemically.

81. The method of claim 77 wherein the white blood cells are administered intravenously.

82. The method of claim 77 wherein the white blood cells express incorporated genetic material of interest.

83. The method of claim 71 wherein the white blood cells are allogeneic.

84. The method of claim 71 wherein the recipient mammalian subject is human.

85. A method of producing differentiated cells from CD34<sup>+</sup> progenitor cells comprising culturing said cells in a culture medium that allows proliferation and differentiation, and contacting said progenitor cells with Actimid™ or Revimid™.

86. The method of claim 85, wherein said contacting is performed on the first day of said culturing.

87. The method of claim 85, wherein said contacting takes place at least twice during the first six days of said culturing.

88. The method of claim 85, wherein said contacting takes place no earlier than said first day of culturing.

89. The method of claim 85, wherein said differentiated cell is a dendritic cell, a granulocyte, a CD34<sup>+</sup>CD38-CD33<sup>+</sup> or a CD34<sup>+</sup>CD38-CD33- cell.

90. The method of claim 85, wherein said CD34<sup>+</sup> progenitor cell is a CD34<sup>+</sup>CD133<sup>+</sup> progenitor cell.

91. The method of claim 85, wherein said differentiated cells are isolated at day 6 of culture.

92. The method of claim 85, wherein said differentiated cells are isolated at day 12 of culture.

93. The method of claim 85, wherein said CD34<sup>+</sup> cells have been isolated from other blood cells prior to said culturing.

94. The method of claim 85, wherein said culture medium additionally contains GM-CSF and TNF- $\alpha$ .

95. The method of claim 85, wherein said Actimid™ is present in a concentration of between 0.1  $\mu$ M and 10.0  $\mu$ M.

96. The method of claim 85 wherein Actimid™ is present at a concentration of 1.0  $\mu$ M.

97. A method of making a pharmaceutical composition, comprising:

- (a) contacting CD34<sup>+</sup> or CD133<sup>+</sup> progenitor cells with a compound that inhibits TNF- $\alpha$  activity, wherein said progenitor cells are cultured for six days under culture conditions that allow proliferation and differentiation of said progenitor cells;
- (b) collecting said cells after six days of culture; and
- (c) placing said cells in a pharmaceutically-acceptable carrier.

98. The method of claim 97 wherein said contacting is performed on the first day of culture.

99. The method of claim 97, wherein said contacting is performed at least twice during said six days of culture.

100. The method of claim 97, wherein said compound is thalidomide or a thalidomide analog.

101. The method of claim 97, wherein said compound is Actimid<sup>TM</sup> or Revimid<sup>TM</sup>.

102. The method of claim 97, wherein said progenitor cells have been isolated from other blood cells prior to said culturing.

103. The method of claim 97, wherein said culture medium additionally contains GM-CSF and TNF- $\alpha$ .

104. The method of claim 101, wherein said Actimid<sup>TM</sup> or Revimid<sup>TM</sup> is present in a concentration of between 0.1  $\mu$ M and 10.0  $\mu$ M.

105. The method of claim 101 wherein said Actimid<sup>TM</sup> or Revimid<sup>TM</sup> is present at a concentration of 1.0  $\mu$ M.

106. The method of claim 6, wherein said cells are cryopreserved after said collecting.

107. A pharmaceutical composition made by the process of claim 97.
